#### Abstract

Haddock catches from eastern Georges Bank fluctuated around 5,000 t from 1985 to 1990. Under restrictive management measures, combined Canada/USA catches declined from over 6,400 t in 1991 to a low of about 2, 100 t in 1995, fluctuated between about $3,000 \mathrm{t}$ and $4,000 \mathrm{t}$ until 1999 and has since increased to over $7,000 \mathrm{t}$.

Adult population biomass (ages $3+$ ) has steadily increased from near an historical low of about $10,000 \mathrm{t}$ in 1993 to about $40,000 \mathrm{t}$ at the beginning of 2001 and 2002 but remains below the average biomass during 1930-55 when productivity was higher. The recent increase was supported by improved recruitment in the 1990's. The exploitation rate for fully recruited ages $4+$ has consistently been below the $\mathrm{F}_{0.1}$ target of $20 \%$ since 1995 . Reduced fishing mortality and avoidance of small fish in the fisheries in recent years has resulted in increased survival of incoming year-classes and greater abundance at older ages.

Projected total Canada/USA yield at $\mathrm{F}_{0.1}=0.25$ in 2002 would be about $10,700 \mathrm{t}$. The adult biomass is projected to increase considerably from about $40,000 \mathrm{t}$ to $54,000 \mathrm{t}$ by the beginning of 2003, largely due to recruitment of the strong 2000 year-class. The population age structure shows good representation at all ages.

## Résumé

Les prises d'aiglefin dans les eaux de l'est du banc Georges ont fluctué aux environs de 5000 t entre 1985 et 1990. Soumises à des mesures de gestion restrictives, les prises canadiennes et américaines combinées ont chuté de plus de 6400 t en 1991 à un creux de d'environ 2100 t en 1995, puis ont fluctué entre environ 3000 et 4000 t jusqu'en 1999, pour ensuite grimper à plus de 7000 t .

La biomasse d'adultes (d'âge 3+) a augmenté régulièrement, passant d'un niveau se rapprochant du creux historique d'environ 10000 t en 1993 à environ 40000 t au début de 2001 et 2002, bien qu'elle demeure inférieure à la biomasse moyenne observée de 1930 à 1955, lorsque la productivité était plus élevée. La récente augmentation de la biomasse est imputable à un meilleur recrutement dans les années 1990. Le taux d'exploitation de l'aiglefin de 4 ans et plus pleinement recruté a toujours été inférieur au taux cible de $\mathrm{F}_{0,1}$ de $20 \%$ depuis 1995 . Un taux réduit de mortalité par pêche et la prévention de la capture de petits poissons dans les dernières années sont à l'origine d'un taux accru de survie des nouvelles classes d'âge et d'une plus forte abondance d'individus âgés.

On prévoit que le rendement total des pêches canadiennes et américaines à $\mathrm{F}_{0,1}=0,25$ en 2002 se chiffrera à environ 10700 t . On prévoit aussi que la biomasse d'adultes augmentera fortement d'ici le début de 2003, pour passer d'environ 40000 t à 54000 t , en grande partie à cause du recrutement de l'abondante classe d'âge 2000. La structure par âge indique en outre que tous les âges sont bien représentés dans la population.

## Introduction

Since 1990, Canada has used eastern Georges Bank, fishery statistical unit areas 5Zej and 5Zem (Figure 1), as the basis for a management unit (Gavaris 1989), referred to as 5Zjm for brevity. This assessment applies the approach used by Van Eeckhaute and Gavaris (2001) using Canadian and USA fisheries information updated to 2001. Results from the Fisheries and Oceans Canada (DFO) survey, updated to 2002, and the USA National Marine Fisheries Service (NMFS) surveys in the spring and fall, updated to 2001, were incorporated.

## The Fishery

## Commercial Catches

Haddock on Georges Bank have supported a commercial fishery since the early 1920s (Clark et al 1982). For details on the historical aspects of the Georges Bank haddock fishery see Gavaris and Van Eeckhaute (1998).

Under restrictive management measures, combined Canada/USA catches declined from over 6,400 t in 1991 to a low of about 2,100 t in 1995, fluctuated between about 3,000 t and $4,000 \mathrm{t}$ until 1999 and has since increased to over 7,000 t (Table 1, Figure 2). Greater catches in the late 1970s and early 1980s, ranging up to about $23,000 \mathrm{t}$, were associated with good recruitment. Substantial quantities of small fish were discarded in those years (Overholtz et al 1983). Catches subsequently declined and fluctuated around 5,000 t during the mid to late 1980s.

Total catches during the 1930s to 1950s ranged between 15,000 t and 40,000 t (Figure 3), averaging about 25,000 t (Schuck 1951, R. Brown pers. com.). Records of catches by unit area for the early 1960s period have not been located, however, based on records for Subdivision 5 Ze , catches probably attained record high levels of about $60,000 \mathrm{t}$ during the early 1960s. Since the early 1970s, catches have been substantially lower, generally fluctuating between $5,000 \mathrm{t}$ and $10,000 \mathrm{t}$.

In 1995 to 1999 and 2001, Canadian catches were below the quota due to closure of some fleet sectors, when the cod quotas were reached. The 2000 catch of $5,402 \mathrm{t}$ was slightly above the Canadian quota of 5,400 t. Since 1994, all Canadian groundfish fisheries on Georges Bank remained closed from January to early June to protect spawning concentrations.

Weight of all Canadian landings were monitored at dockside. At-sea observers monitored $10 \%$ of the 889 trips, which accounted for $14 \%$ of the total haddock landed. In 2001, samples were collected by DFO, observer and by two industry groups, Scotia Fundy Mobile Gear Fishermen's Association and High Liner Foods. Comparison of samples from at sea observations against landings indicated that there was little discarding or highgrading (Fig. 4). Discarding and misreporting have been considered negligible since 1992.

In recent years, the Canadian fishery has been primarily conducted by vessels using otter trawls and longlines with some handlines and gillnets. During 2001, all vessels over 65 ft operated on enterprise allocations, otter trawlers under 65 ft and fixed gear vessels 45-65 ft operated on individual quotas while fixed gear vessels under 45 ft operated on community quotas administered by local boards (Table 2). Most haddock were caught by otter trawlers and longliners in tonnage classes 2 and 3 (Table 3), approximately less than 65 ft . The highest catches occurred in July (Table 4, Figure 5). The Canadian fishery management plan allocations by fleet sector and reported landings are shown below:

| Fishery Sector | 1997 |  | 1998 |  | 1999 |  | 2000 |  | 2001 |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  | Quota | Catch | Quota | Catch | Quota | Catch | Quota | Catch | Quota | Catch |
| Fixed gear $<65^{\prime}$ | 754 | 714 | 915 | 856 | 928 | 902 | 1271 | 1193 | 1731 | 1660 |
| Mobile gear $<65^{\prime}$ | 1625 | 1451 | 1984 | 1997 | 1972 | 1964 | 2743 | 2796 | 3465 | 3432 |
| Fixed gear 65'-100' | 32 | 36 | 39 | 39 | 39 | 8 | 54 | 51 | 70 | 2 |
| Mobile gear 65'-100' | 32 | 35 | 94 | 93 | 188 | 186 | 54 | 224 | 547 | 540 |

USA catches for 2001 were derived from logbooks coupled with dealer reports, as was done for 1994-2000. Effort in the USA fishery was regulated using closed areas and days-at-sea limits (Table 2). To curtail targeting of haddock, a 500 lb trip limit was introduced in 1994 and raised to $1,000 \mathrm{lb}$ in July 1996. The trip limit resulted in an increase in the discard rate. The trip limit has been adjusted periodically and is currently $5,000 \mathrm{lb} /$ day and a maximum of $50,000 \mathrm{lbs} /$ trip. The combination of area closures, effort restrictions, and trip limits has precluded most operators from making long trips to 5 Zjm , with the result that USA catches from 5Zjm have been low since 1993. While Area II remained closed in 2001, landings from 5 Zjm , which come exclusively from tonnage classes 3 and 4 otter trawlers (Table 5), increased to 604 t and discards again were low because the day and trip possession limits remained high. Catches by month were not available for recent years (Table 6).

## Size and Age Composition

The size and age composition of the 2001 Canadian fishery was characterised using port, at sea and industry samples from all principle gears and all seasons. Comparison of length frequencies from these sources did not reveal any persistent differences (Figure 4), therefore, all data was combined (Table 7, Figure 5). The size composition of catch in the Canadian fisheries peaked at $51 \mathrm{~cm}(20 \mathrm{in})$ for otter trawlers and at $58 \mathrm{~cm}(23 \mathrm{in})$ for longliners (Figure 6). Gill-netters caught few haddock but they were larger. No sampling was available for discards of haddock by-catch in the Canadian scallop fishery, though in previous years, the amount caught has not been large.

USA port samples and ageing data from eastern Georges Bank were used to characterise the size and age composition of the USA fishery catch from eastern Georges Bank.

The 2001 catch at age by quarter for Canada and the USA (Table 8) was used to augment the 1969-2000 results (Van Eeckhaute and Gavaris, 2001). Combined Canada/USA annual catch at age and average fishery weights at age are summarized in Tables 9 and 10
and Figure 7. The 1998 year-class (age 3) dominated the 2001 catch. In comparison to the age composition of the catch during periods when year-classes were quickly fished down, the older age groups (ages 7+) continued to contribute significantly to the 2001 catch (Figure 8). The percentage of age 2 fish in 2001 was well below historical averages. The low percentage of younger ages in the recent catches has been due in part to the type of gear used and to avoidance of areas with small fish. The age composition during the 1969 to 1974 period was dominated by the outstanding 1962 and 1963 year-classes which continued to contribute substantially as older fish and is not considered typical.

## Abundance Indices

## Commercial Catch Rates

Catch rates from the Canadian commercial fishery for selected trips (i.e., only those vessels which reported more than 1 t from 5Zjm during 1994 where cod, haddock and pollock comprised over $90 \%$ of the total catch) for tonnage classes 2 and 3 otter trawlers and longliners have generally increased since 1993 (Figure 9). Changes to regulations, gear modifications and varying fishing practices in recent years make comparison of catch rates from year to year difficult to interpret. Therefore, these were not used as indices of abundance.

## Research Surveys

Surveys of Georges Bank have been conducted by DFO each year (February) since 1986 and by NMFS each fall (October) since 1963 and each spring (April) since 1968. All surveys used a stratified random design (Figures 10 and 11). For the NMFS surveys, two vessels have been employed and there was a change in the trawl door in 1985. Vessel and door type conversion factors (Table 11), derived experimentally from comparative fishing, have been applied to the survey results to make the series consistent. Additionally, two trawl nets were used on the NMFS spring survey, a modified Yankee 41 during 1973-81 and a Yankee 36 in other years, but no conversion factors are available for haddock.

The spatial distribution of catches for the most recent surveys of each series was similar to the distribution over the previous 5 year period (Figures 12, 13 and 14). In winter/spring, adults (ages $3+$ ) are more abundant on the Northern Edge but age 1 fish are distributed broadly over the bank. An abundance of age 2 haddock (2000 year-class) was observed on the southern flank during the 2002 DFO survey. In fall, adult haddock are more concentrated in the deeper waters along the slopes of the Northeast Peak and the Northern Edge, however, age 1 fish remain somewhat more widespread.

Age specific abundance patterns from the three surveys track year-class strengths fairly well (Tables 12, 13 and 14; Figure 15). Some year effects are evident, for example, the low spring catches observed for both the 1997 DFO and NMFS surveys. The indices for ages 3-8 survey biomass peaked at record highs during the early 1960s (Figure 16). After declining to a record low in the early 1970s, they peaked again in the late 1970s, though at a lower level, and again during the mid to late 1980s at about half the level of the

1970s peak. Biomass generally increased during the 1990s, and has fluctuated somewhat in recent years.

Survey recruitment indices for ages 0,1 and 2 indicate that the abundance of the 2000 year-class is comparable to the good 1975 and 1978 year-classes, with the 1998 yearclass being the second strongest since the 1978 (Figure 17). The 1996 and the 1999 yearclasses were comparable to the moderate 1983, 1985, 1987 and 1992 year-classes. These year-classes were considerably smaller than the strong 1975 and 1978 year-classes and the exceptional 1963 year-classes. Early indications from survey results suggest that the 2001 year-class is weak.

Although fishery weights at age (Table 10, Figure 19) for ages 2 and 3 are higher since 1993/1994, reflecting the change in gear selectivity which occurred, there have been no persistent trends in population weight at age derived from the DFO surveys. The survey weights at age (Table 15, Figure 18) for 2002, while generally within the range of observation, were notably lower than for 2001. Average weight at age of haddock from the 1989, 1990 and 1991 year-classes were higher than adjacent year-classes in both the surveys and the commercial fisheries, giving the false impression of a declining trend in recent years. The method of calculation of the weights at age from the DFO survey, which were used for beginning of year population weights, are given in Gavaris and Van Eeckhaute (1998) and were derived from weights observed during the survey, weighted by population numbers at length and age. Fishery weights at age are derived from a length-weight relationship (Waiwood and Neilson 1985). In some cases, the mean weight at age in the catch is larger than the population mean weight at age at the beginning of the following year for the same cohort. This feature was mostly attributable to bottom trawl gear changes which resulted in a change in partial recruitment since 1994 (Gavaris and Van Eeckhaute, 2000). However, some discrepancies in weights at age were more persistent and may be due to problems associated with the length weight equations and gutted to round weight conversion factors.

## Estimation of Stock Parameters

## Calibration of Virtual Population Analysis (VPA)

The adaptive framework, ADAPT, (Gavaris 1988) was used to calibrate the virtual population analysis with the research survey abundance information. An investigation of model formulations and model assumptions was conducted by Gavaris and Van Eeckhaute (1998) where details of model equations and the objective function are provided. The model formulation adopted assumed that the random error in the catch at age was negligible. The errors in the abundance indices were assumed independent and identically distributed after taking natural logarithms of the values. The annual natural mortality rate, M , was assumed constant and equal to 0.2 . Similar model assumptions and methods were applied to the updated information here. Minor differences in the handling of zero terminal catches for a year-class were implemented as a refinement to the software to afford more flexibility. The population abundance for the $9+$ age group was calculated but not calibrated to the indices. In the first quarter of the first year, the 9+ abundance calculation was based on the assumption that the fishing mortality for the 9+
age group was equal to the population weighted fishing mortality for ages $4-8$. In the first quarter of subsequent years, the $9+$ abundance was calculated as the sum of the age 8 and age group $9+$ abundances at the end of the last quarter of the previous year.

The VPA used quarterly catch at age, $C_{a, t}$, for ages $a=0,1,2 \ldots 8,9+$, and time $t=$ 1969.0, 1969.25, 1969.5, 1969.75, 1970.0...2001.75, where $t$ represents the beginning of the time interval during which the catch was taken. The VPA was calibrated to bottom trawl survey abundance indices, $I_{s, a, t}$, for
$s=$ DFO spring, ages $a=1,2,3 \ldots 8$, time $t=1986.16,1987.16 \ldots .2001 .16,2002.0$
$s=$ NMFS spring (Yankee 36), ages $a=1,2,3 \ldots 8$, time $t=1969.29,1970.29,1971.29$, 1972.29, 1982.29, 1983.29...2001.29
$s=$ NMFS spring (Yankee 41), ages $a=1,2,3 \ldots 8$, time $t=1973.29,1974.29 \ldots 1981.29$
$s=$ NMFS fall, ages $a=0,1,2 \ldots 5$, time $t=1969.69,1970.69 \ldots 2001.69$
Since forecast projections were required for the entire year 2002, the DFO spring survey in 2002 was designated as occurring at time 2002.0 instead of 2002.16. The NMFS fall survey captures young of the year and that information is included as 0 group, but older haddock appear less available during this season. Survey indices for older ages where catches were sparse and where there were frequent occurrences of zero catches were not included. Zero observations for abundance indices were treated as missing data as the logarithm of zero is not defined. During years when discarding was high, survey information was used along with interviews to obtain estimates of the USA catch. This lack of complete independence between catch and survey data does not influence population estimates but may deflate variance estimates marginally.

Statistical properties of estimators were obtained from model conditioned non-parametric bootstrap of the residuals (Efron and Tibshirani 1993) as described in Gavaris and Van Eeckhaute (1998). The population abundance estimates show a large relative error and substantial bias at ages 1 while the relative error for other ages is between about $30 \%$ and $45 \%$ and the bias is smaller (Table 16). The average magnitude of residuals is large and though several large residuals can be identified, the respective observations do not appear influential and should not impact parameter estimates of current abundance (Figures 2024). Some patterns in the residuals (by cohort and by age) merit further investigation.

## Retrospective Analysis

Assessment results for several other stocks have identified a discrepancy between past and current estimates of stock status (retrospective pattern). This stock assessment does not suffer from a retrospective pattern. Successive estimates of year-class abundance at age are fairly stable (Figure 25) although there is sometimes a substantial change after the first estimate of a year-class when more data becomes available, as evidenced for the 1992 and 1996 year-classes. There were no trends of concern for adult biomass (ages 3-8) or for F (ages $4-8$ weighted by population numbers) in the retrospective patterns (Figure 26).

## Stock Status

The results from the calibrated VPA were considered appropriate on which to base the status of the stock. For each cohort, the terminal population abundance estimates from ADAPT were adjusted for bias and used to construct the history of stock status (Tables 17-18). This approach for bias adjustment, in the absence of an unbiased point estimator with optimal statistical properties, was considered preferable to using the biased point estimates (O'Boyle 1998). Bias adjusted VPA results were based on bootstrap statistics. The weights at age from the DFO spring survey (Table 15) were used to calculate beginning of year population biomass (Table 19). A weight of 2.4 kg , which was midway between the age 6 and 8 weight for that cohort, was used for age 7 in 1995 as no data were available for that age group. For 1969-85, the 1986-95 average weight at each age was used.

Population biomass (ages 3+) has steadily increased from near an historical low of about $10,000 \mathrm{t}$ in 1993 to about 40,000 t at the beginning of 2001 and 2002 (Figure 27). The $12 \%$ drop from 2001 to 2002, was due in part to lower weights at age. The recent increase has been due to more consistent and improved recruitment and was enhanced by increased survivorship and by reduced capture of small fish in the fisheries. Since the 1991 year-class, only the 2001 year-class has been below 5 million fish. Between the 1978 and 1991 year-classes, 7 of the 14 year-classes were below 5 million fish. The biomass increase is expected to be sustained by the 2000 year-class. Total biomass (ages $1+$ ) trend is similar to the ages $3+$ trend.

Population biomass during the late 1970s and early 1980s was about $50,000 \mathrm{t}$, due to recruitment of the strong 1975 and 1978 year-classes whose abundance was estimated at about 50 million. However, biomass declined rapidly in the early 1980s as subsequent recruitment was poor and these two year-classes were fished intensely at a young age.

Recruitment, estimated by the VPA, indicate that the 2000 year-class ( 48 million at age 1) is about equal in strength to the good 1975 and 1978 year-classes (Figure 28). The 1998 year-class ( 25 million at age 1) is the second strongest since that of 1978. The 1996 and 1999 year-classes were estimated to be about 13 million, comparable to the 1983, 1985 and 1987 year-classes, which were the strongest 3 year-classes over about a 20 year time span.

Exploitation rate on fully recruited ages $4+$ has consistently been below that corresponding to $\mathrm{F}_{0.1}(20 \%)$ since 1995 (Figure 29). Historically, exploitation rate has generally exceeded that corresponding to $\mathrm{F}_{0.1}$ and showed a marked increase between 1989 and 1993 to about $40 \%$, the highest observed. Reduced fishing mortality in recent years has resulted in increased survival of incoming year-classes. The number of haddock of the 1992 year-class surviving to age 8 was about four times that of the equally abundant 1983 year-class, and about the same as that of the 1975 or 1978 year-classes, which were more than 3 times as abundant (Figure 30). Fishery avoidance of small fish has resulted in the number of fish of the 1998 year-class surviving to age 3 to be almost as many as survived to age 3 of the 1978 year-class which was twice as strong. In both absolute numbers and percent composition, the population structure displays a broad
representation of age groups, reflecting improving recruitment and lower exploitation since 1995 (Figure 31).

Gains in fishable biomass may be partitioned into those associated with somatic growth of haddock, which have previously recruited to the fishery, and those associated with new recruitment to the fishery (Rivard 1980). We used age 2 as a convenient age of first recruitment to the fishery. Except for 2001, since 1993 surplus production (biomass gains from growth and from recruitment, decremented by losses due to natural deaths) has exceeded the fishery harvest yield, resulting in net increase (Figure 32). Growth of fish is the dominant component of the biomass gain but recruitment accounts for significant portions when stronger year-classes enter the population. (Figure 33).

## Prognosis

Yield projections were done using the bias adjusted 2002 beginning of year population abundance estimates. The abundance of the 2002 year-class was assumed to be 10 million at age 0 . For the forecast, partial recruitment to the fishery for ages 1,2 and 3 and fishery weights at age were averaged over 1997 to 2001 while beginning of year population weights were those observed in 2002 (Table 20). Projected total Canada/USA yield at an exploitation rate of $20 \%$ corresponding to $\mathrm{F}_{0.1}=0.25$ in 2002 would be about $10,700 \mathrm{t}$ (Figure 34). If fished at that rate in 2002, the adult biomass is projected to increase considerably from about $40,000 t$ to $54,000 t$ by the beginning of 2003, largely due to recruitment of the 2000 year-class. The 1998 year-class (age 4 ) is expected to comprise the highest proportion of the total 2002 yield, accounting for about $40 \%$.

Uncertainty about year-class abundance generates uncertainty in forecast results. This was expressed as risk of achieving reference levels. For example, a combined Canada/USA catch of $8,000 \mathrm{t}$ in 2002 would be required to obtain a low probability (less than $10 \%$ ) that fishing mortality rate will exceed $\mathrm{F}_{0.1}$ (Figure 35). At this yield, there is a negligible probability of not achieving a $10 \%$ or $20 \%$ biomass increase.

These uncertainties are dependent on the model assumptions and data used in the analyses. Though these assumptions were deemed most suitable, there may be other plausible assumptions. These calculations do not include uncertainty due to variations in weight at age, partial recruitment to the fishery, natural mortality, systematic errors in data reporting or the possibility that the model may not reflect the stock dynamics closely enough. The risk profiles provide a general sense of the associated uncertainties and can assist in assessing the consequences of alternative actions.

## Management Considerations

The Canadian quota of $6,989 \mathrm{t}$ in 2001 was expected to result in a negligible chance of exceeding $\mathrm{F}_{0.1}$ but there was a low chance of achieving $10 \%$ growth. The Canadian catch in 2001 was very near the quota and resulted in an exploitation rate of about $17 \%$ and a decrease in adult biomass of about $12 \%$ from 2001 to 2002 .

Data were available to approximate the age composition of the catch from unit areas 5 Zj and 5 Zm in order to reconstruct an illustrative population analysis for the period between 1930 and 1955 suitable for comparison of productivity. Total catches during the 1930s to 1950s ranged between $15,000 \mathrm{t}$ and $40,000 \mathrm{t}$, averaging about $25,000 \mathrm{t}$. Catches probably attained record high levels of about 60,000 $t$ during the early 1960s. Since the early 1970s, catches have been substantially lower, generally fluctuating between $5,000 \mathrm{t}$ and $10,000 \mathrm{t}$. Although biomass has been increasing and is the highest it has been in about 30 years, it remains below the average biomass during 1930-55, when productivity was higher (Figure 36).

The pattern of recruitment indicates that the chance of a strong year-class is significantly reduced for adult biomass below about 40,000 t (Figure 37). Since 1969, only the 1975, 1978 and 2000 year-classes have been above the average abundance of year-classes observed during the period 1930-55. Examination of the recruits per adult biomass ratio suggests that survivorship to age 1, for several years during the 1980s, may have been lower than the norm (Figure 38). The present survivorship appears comparable to that of the 1930s to 1950s period, suggesting that higher recruitment might result if the biomass increases.

Exploitation rate and biomass can be used to compare consequences of alternative harvest yields. The projections above show those results. Other attributes like recruitment, age structure and spatial distribution reflect possible fluctuations in the productive potential and can be used to qualify reference points and acceptable risk. While conditions have improved, maintaining exploitation rate at current levels would enhance further rebuilding.

Consistent management by Canada and the USA is required to ensure that conservation objectives are not compromised.

Cod and haddock are often caught together in Canadian groundfish fisheries. However, their catchabilities to the fisheries differ and they are not necessarily caught in proportion to their relative abundance. With current fishing practices, exploitation of haddock at $\mathrm{F}_{0.1}$ may compromise the achievement of rebuilding objectives for cod.

## Acknowledgements

We are grateful to staff at the Northeast Fisheries Science Center in Woods Hole, MA, and in particular R.W. Brown, for providing information from the USA fishery and the NMFS surveys and for their assistance in interpretation of that data. G. Donaldson, E. Williams and several industry groups provided samples from the Canadian fishery. We thank members of the fishing industry who spent time to discuss their experiences in the fishery and Mike Power for providing valuable comments during his review of the draft version.

Table 2. Regulatory measures implemented for the 5 Z and 5 Zjm fishery management units by the USA and Canada, respectively, from 1977, when jurisdiction was extended to 200 miles for coastal states, to the present.

|  | USA | Canada |
| :---: | :---: | :---: |
| 1977-82 | Mesh size of $51 / 8^{\prime \prime}(140 \mathrm{~mm})$, seasonal spawning closures, quotas and trip limits. |  |
| 1982-85 | All catch controls eliminated, retained closed area and mesh size regulations, implemented minimum landings size ( 43 cm ). | First 5Ze assessment in 1983. |
| 1984 Oct. | Implementation of the 'Hague' line . |  |
| 1985 | $51 / 2 "$ mesh size,. <br> Areas 1 and 2 closed during February-May. |  |
| 1989 |  | Combined cod-haddock-pollock quota for 4X-5Zc |
| 1990 |  | $\mathbf{5 Z j m}$ adopted as management unit. <br> For MG $<65 \mathrm{ft}$. - trip limits with a $30 \%$ by-catch of haddock to a maximum of 8 trips of $35,000 \mathrm{lbs}$ per trip between June 1 and Oct. 31 and 130 mm square mesh required. <br> Fixed gear required to use large hooks until June |
| 1991 | Established overfishing definitions for haddock. | MG $<65 \mathrm{ft}$ similar to 1990 but mesh size increased to 145 mm diamond. |
| 1992 |  | Introduction of ITQs and dockside monitoring. |
| 1993 | Area 2 closure in effect from Jan 1-June30. | OT fishery permitted to operate in Jan. and Feb. Increase in use square mesh. |
| 1994 | Jan.: Expanded Area 2 closure to include June and increased extent of area. <br> Area 1 closure not in effect. <br> 500 lb trip limit. <br> Catch data obtained from mandatory log books combined with dealer reports (replaces interview system). <br> May: 6" mesh restriction. <br> Dec.: Area 1,2 closed year-round. | Spawning closure extended to Jan. 1 to May 31. <br> Fixed gear vessels must choose between 5 Z or 4 X for the period of June to September. <br> Small fish protocol. <br> Increased at sea monitoring. <br> OT $>65$ could not begin fishng until July 1 . <br> Predominantly square mesh by end of year. |
| 1995 |  | All OT vessels using square mesh. Fixed gear vessels with a history since 1990 of $25 t$ or more for 3 years of cod, haddock pollock, hake or cusk combined can participate in 5 Z fishery. <br> ITQ vessel require at least 2 t of cod and 8 t of haddock quota to fish Georges. |
| 1996 | July: Additional Days-at-Sea restrictions, trip limit raised to 1000 lbs . | Fixed gear history requirement dropped. |
| 1997 | May: Additional scheduled Days-at-sea restrictions. September: Trip limit raised to $1000 \mathrm{lbs} /$ day, maximum of $10,000 \mathrm{lbs} /$ trip. | Vessels over 65 ft operated on enterprise allocations, otter trawlers under 65 ft on individual quotas, fixed gear vessels $45-65 \mathrm{ft}$ on self-administered individual quotas and fixed gear vessels under 45 ft on community quotas administered by local boards. |
| 1998 | Sept. 1: Trip limit raised to $3000 \mathrm{lbs} /$ day, maximum of $30,000 \mathrm{lbs} /$ trip. | Fixed gear vessels $45-65 \mathrm{ft}$ operated on individual quotas. |
| 1999 | May 1: Trip limit 2,000 lbs/day, max. 20,000 lbs/trip. Square mesh size increased to $6.5^{\prime \prime}$ (diamond is $6 "$ ). June 15: Scallop exemption fishery in Closed Area II. Nov. 5: Trip limit 5,000 lbs/day, max. $50,000 \mathrm{lbs} /$ trip. | Same as 1997 and 1998. |
| 2000 | October: Daily trip limit suspended to April 2001but retained max. trip limit of $50,000 \mathrm{lbs} /$ trip. | Same as 1999. |
| 2001 | Similar to 2000 with day and trip limit adjustments. | Same as 2000. |

${ }^{1}$ Average of 1997 - 2001.
${ }^{2}$ Equal to 2002 from DFO survey.
${ }^{3}$ Equal to 2001 from fishery.

Figure 1. Fisheries statistical unit areas in NAFO Subdivision 5Ze.

Figure 2. Nominal catch of haddock in unit areas 5 Zjm .

Figure 3. Historic catch of haddock in 5Zjm compared to recent catches.

Figure 4. Comparison of length frequencies obtained at port and at sea from the Georges Bank commerical fishery in 2001. The number of fish measured is shown in brackets.

Figure 4. continued

Figure 5. Haddock catches in 5Zjm by month and gear for the Canadian commercial fishery in 2001 (wide gray bars) with sampling levels (narrow black bars).

Figure 6. Catch at length by the principal Canadian 5Zjm commercial haddock fisheries in 2001.

Figure 7. Total commercial catch at age (numbers) of haddock from unit areas 5 Zjm . The bubble area is proportional to magnitude (see Table 9).

Figure 8. Age composition of the haddock catch for the Canadian 5Zjm commercial fishery in 2001 compared to the average age composition for the total catch of all fisheries during three earlier periods.

Figure 9. Catch rates for haddock from the Canadian commercial fishery in 5 Zjm . ( $\mathrm{LL}=$ longline, $\mathrm{OT}=$ otter trawl, $\mathrm{TC}=$ tonnage class).

Figure 10. Stratification scheme used for NMFS surveys. The 5Zjm management area is indicated by shading.

Figure 11. Stratification scheme used for the DFO survey. The 5 Zjm management area is indicated by shading.

Figure 12. Distribution of 5 Zjm haddock abundance (number/tow) as observed from the DFO survey. The squares are shaded relative to the average catch for 1997 to 2001 . The expanding symbols represent the 2002 survey catches.

Figure 13. Distribution of 5 Zjm haddock abundance (number/tow) as observed from the NMFS spring survey. The squares are shaded relative to the average catch for 1996 to 2000 . The expanding symbols represent the 2001 survey catches.

Figure 14. Distribution of 5Zjm haddock abundance (number/tow) as observed from the NMFS fall survey. The squares are shaded relative to the average catch for 1996 to 2000 . The expanding symbols represent the 2001 survey catches.

Figure 15. Estimated abundance at age (numbers in 000 's) of haddock for the DFO and NMFS spring surveys and the NMFS fall survey. Bubble area is proportional to magnitude (see Tables 12-14). Conversion factors to adjust for changes in door type and survey vessel were applied to the NMFS surveys. From 1973-81 (pale circles), a 41 Yankee trawl was used for the NMFS spring survey while a 36 Yankee was used in the other years. Symbol size has not been adjusted between surveys for the catchability of the survey.

Figure 16. Biomass from NMFS fall (ages 2-8), NMFS spring (ages 3-8) and DFO (ages 3-8) research surveys (scaled by calibration constants, Table 16) for haddock in unit areas 5 Zjm ..

Figure 17. Year-class abundance for ages 0 and 1 from the NMFS fall and ages 1 and 2 from the NMFS and DFO spring research surveys (scaled by calibration constants, Table 16) for haddock in unit areas 5 Zjm .

Figure 18. Weight at age for haddock in unit areas 5 Zjm derived from the DFO spring surveys.

Figure 19. Weight at age for haddock in unit areas 5 Zjm derived from the commercial fisheries.

Figure 20. Residuals by year and age group for each research survey index. Solid symbols indicate positive values, open symbols indicate negative values. Bubble area is proportional to magnitude. From 1973-81 (pale circles), a 41 Yankee trawl was used for the NMFS spring survey while a 36 Yankee was used in the other years.

Figure 21. Age by age plots of the observed and predicted $\ln$ abundance index versus $\ln$ population numbers for haddock in unit areas 5 Zj and 5 Zm from the DFO survey.

Figure 22. Age by age plots of the observed and predicted $\ln$ abundance index versus $\ln$ population numbers for haddock in unit areas 5 Zj and 5 Zm from the NMFS spring survey with a Yankee 36 net.

Figure 23. Age by age plots of the observed and predicted $\ln$ abundance index versus $\ln$ population numbers for haddock in unit areas 5 Zj and 5 Zm from the NMFS spring survey with a Yankee 41 net.

Figure 24. Age by age plots of the observed and predicted $\ln$ abundance index versus $\ln$ population numbers for haddock in unit areas 5 Zj and 5 Zm from the NMFS fall survey.

Figure 25. Successive estimates of 5Zjm haddock year-class abundance as additional years of data were included in the assessment did not display any persistent trends.

Figure 26. Retrospective estimates from VPA of 5Zjm haddock biomass and fishing mortality did not display any persistent trends for over or under estimation as successive years of data were excluded in the assessment.

Figure 27. Beginning of year total (1+) and adult (3+) biomass for haddock in unit areas 5 Zjm .

Figure 28 . Number of age 1 recruits for haddock in unit areas 5 Zjm .

Figure 29. Exploitation rate for haddock ages $4+$ in unit areas 5 Zjm and the exploitation rate (20\%) at $\mathrm{F}_{0.1}$.

Figure 30. Decay of selected year-classes of the 5 Zjm haddock population.

Figure 31. The age composition and absolute abundance at age of the 5Zjm haddock population in 2001 compared to earlier periods.

Figure 32. Surplus production of 5 Zjm haddock available to the commercial fishery compared to the harvested yield.

Figure 33. Amount of productivity attributible to growth (ages 2 to $9+$ ) of 5 Zjm haddock and the amount contributed by recruitment (age 2 ).

Figure 34. Expected exploitation rate in 2002 and expected change in biomass from 2002 to 2003 for 5Zjm haddock at various quotas.

Figure 35. Probability of 2002 explopitation rate exceeding $20 \%$, the $\mathrm{F}_{0.1}$ reference level, and of the 2003 ages $3+$ biomass being less than the 2002 biomass by $0 \%, 10 \%$ and $20 \%$ for 5 Zjm haddock at various quotas.

Figure 36. Historical catch and total biomass of haddock in 5 Zjm compared to recent catches and biomass.

Figure 37. Relationship between adult (ages 3+) 5Zjm haddock biomass and recruits at age 1 from 1931 to 1955 and 1969 to 2001.

Figure 38. Ratio of recruits (numbers at age 1) to spawning biomass ( kg ) for 5 Zjm haddock suggests that, except for 2001, present survivorship appears comparable to that of the 1930s to 1950s.

[^0]:    ${ }^{1}$ Total includes catches for tonnage classes which are not listed, only tonnage classes with substantial catches listed
    ${ }^{2}$ Catches of 26t, 776t, 1091t and 2 t for side otter trawlers and stern otter trawlers tonnage classes 2,3 and 5 respectively were excluded because of suspected area misreporting.

[^1]:    ${ }^{1}$ Catches of 3t, 1846t and 46t for Jan., Feb., and Mar., respectively for otter trawlers were excluded because of suspected area misreporting
