## Canadä'

#### Abstract

The total catch of eastern Georges Bank haddock in 2003 was $8,431 \mathrm{mt}$. This included estimated discards from the Canadian scallop fishery, which were very low relative to the total catch. The Canadian catch increased slightly from 6,525 in 2002 to $6,867 \mathrm{mt}$ in 2003 while the USA catch increased substantially from 914 mt in 2002 to $1,564 \mathrm{mt}$ in 2003. Eastern Georges Bank haddock catches fluctuated around $5,000 \mathrm{mt}$ during 1985-1990. Under restrictive management measures, combined Canada/USA catches declined from over 6,400 mt in 1991 to a low of about 2,100 mt in 1995, averaged about 3,600 mt during 1996-1999 and have increased since then.

Adult population biomass has steadily increased from near an historical low of about 8,700 mt in 1993 to about $76,000 \mathrm{mt}$ at the beginning of 2004. Eastern Georges Bank haddock biomass is now well within the range observed during 1931 to 1955 when the stock was more productive. Three strong year classes have been produced in recent years. The 2003 year class may be comparable to the outstanding 1963 year class. The 2000 year class is estimated to be larger than the strong 1975 and 1978 year classes and the 1998 year class is the third strongest since 1979. Fishing mortality has been below the reference threshold (Fref) of 0.26 since 1995. Reduced fishing mortality and lower bycatches of juveniles have increased haddock survival rates and led to greater abundance of older fish. The population age structure shows full representation of all age classes.

With an assumed total catch of $15,000 \mathrm{mt}$ in 2004, a combined Canada/USA catch of 26,000 mt in 2005 would result in a neutral risk (50\%) that fishing mortality in 2005 would exceed Fref. A catch of 23,000 mt would result in a low risk (25\%) that fishing mortality in 2005 would exceed Fref. Catches in 2006 are expected to increase substantially as the 2003 year class becomes more fully recruited to the fishery.

## RÉSUMÉ

Les prises totales d'aiglefin dans l'est du banc Georges en 2003 se chiffraient à 8431 t , y compris les prises estimées rejetées en mer par les pétoncliers canadiens, très faibles par rapport aux prises totales. De 2002 à 2003, les prises canadiennes ont légèrement augmenté, passant de 6525 t à 6867 t , alors que les prises américaines ont nettement augmenté, passant de 914 t à 1564 t . Les prises d'aiglefin dans ce secteur ont fluctué autour de 5000 t de 1985 à 1990. Sous le coup de mesures de gestion restrictives, le total des prises canadiennes et américaines a chuté, passant de plus de 6400 t en 1991 à un creux d'environ 2100 t en 1995, pour ensuite augmenter, se situant en moyenne à environ 3600 t de 1996 à 1999; cette tendance se poursuit.

De près d'un creux historique d'environ 8700 t en 1993, la biomasse d'adultes dans le secteur est du banc Georges a régulièrement augmenté, pour se chiffrer à quelque 76000 t au début de 2004; elle se situe maintenant largement dans la plage observée de 1931 à 1955, période pendant laquelle le stock était plus productif. Trois abondantes classes d'âge se sont manifestées dans les dernières années: celle de 2003 pourrait être tout aussi abondante que l'exceptionnelle classe d'âge 1963, celle de 2000 est estimée comme étant plus abondante que les fortes classes d'âge 1975 et 1978 tandis que celle de 1998 est la troisième plus abondante depuis 1979. Le taux de mortalité par pêche est inférieur au taux de référence cible ( $\mathrm{F}_{\text {reff }}$ ) de 0,26 depuis 1995. Le taux réduit de mortalité par pêche et des prises accessoires de juvéniles plus faibles ont résulté en un taux de survie accru et une plus forte abondance d'individus âgés. Toutes les classes d'âge sont représentées dans la structure des âges de la population.

À un niveau supposé de prises totales de 15000 t en 2004, il est peu probable que des prises canadoaméricaines combinées de 26000 m en 2005 résulteraient en un taux de mortalité par pêche cette année-là supérieur à $F_{\text {réf, }}$, alors que des prises de 23000 t résulteraient en un risque faible ( $25 \%$ ). On s'attend à ce que les prises en 2006 augmentent considérablement car la classe d'âge 2003 sera davantage recrutée à la pêche.

## INTRODUCTION

Since 1990, Canada uses eastern Georges Bank, statistical unit areas $j$ and $m$ in NAFO sub-division 5Ze (Figure 1), as a haddock management unit (Gavaris 1989), referred to as " 5 Zjm". Canada and the USA jointly develop management measures for Georges Bank transboundary stocks including haddock. The 5Zjm management unit was adopted as the basis for a harvest allocation proposal for the two countries (DFO 2002). This assessment applies the approach used by Van Eeckhaute et al (2003) using Canadian and USA fisheries information updated to 2003. Results from the Fisheries and Oceans Canada (DFO) survey, updated to 2004, and the USA National Marine Fisheries Service (NMFS) surveys in the spring, updated to 2004, and fall, updated to 2003, were incorporated.

## FISHERY

## Commercial Catches

Haddock on Georges Bank have supported a commercial fishery since the early 1920s (Clark et al 1982, Gavaris and Van Eeckhaute 1998). Catches during the 1930s to 1950s ranged between 15,000 mt and 40,000 mt (Figure 2), averaging about 25,000 mt (Schuck 1951, R. Brown pers. com.). Records of catches by unit area for the early 1960s period have not been located, however, based on records for NAFO Subdivision 5Ze, catches probably attained record high levels of about 60,000 mt during the early 1960s. Catches in the late 1970s and early 1980s, ranging up to about 23,000 mt, were associated with good recruitment. Substantial quantities of small fish were discarded in those years (Overholtz et al 1983). Catches subsequently declined and fluctuated around 5,000 mt during the mid to late 1980s. Under restrictive management measures in recent years, combined Canada/USA catches declined from over $6,400 \mathrm{mt}$ in 1991 to a low of about 2,100 mt in 1995, fluctuated between about $3,000 \mathrm{mt}$ and 4,000 mt until 1999 and have since increased to over 8,000 mt (Table 1, Figure 3). For 2003 the Canadian catch was $6,867 \mathrm{mt}$ and the USA catch was 1564 mt .

Quotas are the principal means used to regulate the Canadian groundfish fisheries on Georges Bank. Canadian catches since 1995 were below the quota due to closure of some fleet sectors when the cod quotas were reached, except for the year 2000 when the catch of $5,402 \mathrm{mt}$ was slightly above the Canadian quota of $5,400 \mathrm{mt}$. Quota regulation requires effective monitoring of fishery catch. Weights of all Canadian landings in 2003 were monitored at dockside and at-sea observers monitored $9 \%$ by weight of the haddock caught in 2003. Discarding and misreporting of haddock by the groundfishery have been considered negligible since 1992. Since 1994, all Canadian groundfish fisheries on Georges Bank have remained closed from January to early June.

In recent years, the Canadian fishery has been conducted primarily by vessels using otter trawls and longlines with some handlines and gillnets. During 2003, otter trawlers under 65 ft and fixed gear vessels $45-65 \mathrm{ft}$ operated on individual quotas while fixed gear vessels under 45 ft operated on community quotas administered by local boards (Table 2). Vessels over 65 ft operate on Enterprise Allocations, which are company quotas. Smaller vessels are allowed to fish the quota which has been allocated to the larger vessels under the Temporary Vessel Replacement Program (TVRP) and increasing amounts of this quota have been taken by the TVRP boats in recent years. In 2003, no otter trawlers greater than 65 ft participated in the haddock fishery. Most haddock were caught by otter trawlers and longliners in tonnage classes 2 and 3 (less than 150 tons) vessels less than 65 ft in overall length, two thirds by the otter trawlers and one third by the longliners (Table 3). The highest catches in 2003 occurred during July (Table 4, Figure 4).

Canadian landings until 1995 include those catches reported by the scallop fishery but, since 1996, this fishery has been prohibited from landing haddock and this species was then discarded. Haddock bycatch, when landings were allowed, was low with a maximum of 41 mt reported (Table 3). Discards of haddock from this fishery for 1996 to 2000 were estimated from scallop effort data and bycatch rates from observed trips conducted in 1994, 1995 and 1998 and ranged between 21 and 54 mt (Table 1). In 2001-2002, a monitoring program was conducted by the Canadian offshore scallop industry to examine bycatch of several species, including haddock. Twelve observer deployments on offshore scallop vessels were conducted between May 2001 and April 2002. Discards from this fishery in 2001 to 2003 are estimated to be 50, 36 and 78 mt , respectively (Appendix A).

USA haddock catches for 2003 were derived from mandatory dealer reports and fishing vessel logbooks using the same procedures as for 1994-2002. The USA fishery has been regulated using trawl mesh size increases, closed areas, days-at-sea limits, and trip limits (Table 2). Trip limits were introduced in 1994 and daily catch limits in 1996 to reduce fishing mortality. Low trip limits in the mid-1990s resulted in an increase in discards which were included in the USA catch at age data. Trip limits have been adjusted periodically to reduce discarding of haddock and improve haddock yields by increasing the limits. In 2003 the daily trip limit was suspended on May 1 and the 50,000 lbs trip cap was removed Oct 3 . The combination of area closures, effort restrictions, and trip limits reduced USA fishing effort in 5Zjm, with the result that USA catches from 5Zjm were relatively low from 1993 to 2000. Even though Area II was closed, landings from 5Zjm, which come almost exclusively from tonnage classes 3 and 4 otter trawlers ( 50 to 500 tons), more than doubled from 604 mt in 2001 to 1,564 mt in 2003 (Table 5). Discards have remained low because of high trip limits combined with larger trawl mesh size. Catches by month have not been available since mandatory reporting began in 1994 (Table 6). Quarterly USA landings totals in 2003 were: 180 (11\%), 1041 (67\%), 92 (6\%) and 251 mt (16\%) (Table 7). USA landings were divided into 656 mt (42\%) large, 893 mt (57\%) scrod and 15 mt (1\%) unclassified market categories.

## Size and Age Composition

The size and age composition of the 2003 Canadian fishery was characterized using port, at-sea and industry samples from all principal gears and seasons. Samples were collected by DFO, observers and by an industry group, Scotia Fundy Mobile Gear Fishermen's Association. Comparison of length frequencies from these sources did not reveal any persistent differences (Figure 5), therefore, all data was combined (Table 8). The size composition of catch in the Canadian fisheries peaked at $51 \mathrm{~cm}(20 \mathrm{in})$ for otter trawlers and at $57 \mathrm{~cm}(22 \mathrm{in})$ for longliners (Figure 6). Gill-netters caught few haddock but they were larger. Haddock discards from the Canadian scallop fishery have not yet been processed with respect to size/age composition. Therefore, these discards are not included in the catch at age. The amount of discards estimated is minimal and, in previous years, landings from this fishery were small so omitting catches from this source should not unduly impact the results from analyses.

Length samples from USA 5Zjm landings in 2003 were inadequate to characterize the fishery by quarter since no scrod samples were collected in quarters 1 and 3 (Table 7). As a result, size composition data were augmented by length samples from adjacent areas (522 (5Zh) and 525 ( 5 Zn )) with similar size compositions. Quarterly age samples were also inadequate and USA age composition data was augmented with 2003 DFO survey data for quarter 1 and with the 2003 Canadian commercial fishery age length keys for quarters 2, 3, and 4. The weight composition of the USA 5Zjm landings by market category was $42 \%$ large, peaking at 62 cm and $58 \%$ scrod, peaking at 55 cm . The scrod market category length samples did not contain any fish below 44 cm which is the minimum size limit for haddock in USA landings.

Ages of survey and commercial-caught haddock were separately assigned by DFO and NMFS age readers. Intra-reader agreement tests for the DFO reader conducted in 2003 indicated that age interpretations were internally consistent (Table B1). Intra-reader agreement for the NMFS haddock reader was generally good although there was some tendency for discrepancies to be in the same direction for haddock samples collected during quarters 1 and 2 (Table B2 and B3). Agreement between the DFO reader and the NMFS reader was acceptable (Table B4). Overall, age reader agreement was judged to be adequate for estimating catch at age.

The 2003 Canadian and USA catch at age estimates by quarter (Table 9) were added to the 1969-2002 catch at age data (Van Eeckhaute et al 2003). Although revised Canadian and USA landings were available for 2002, no adjustment to the 2002 catch at age was made as Canadian landings were still preliminary and the proration of USA landings by area have not been finalized. Combined Canada/USA annual catch at age and average fishery weights at age are summarized in Tables 10 and 11 and Figure 7 and 8. The 2000 year class (age 3) dominated the Canadian 2003 catch with the 1998 year class (age 5) contributing a high percentage. The USA catch was dominated by the 1998 year class with the 1996 and the 2000 year classes contributing. In comparison to the age composition of the catch during periods when year classes were quickly fished down, the older age groups (ages 9+) continued to contribute significantly to the 2003 catch (Figure 9). The low percentage of younger ages in the recent catches has been due in part to the type of gear used and to avoidance of areas with small fish. The age composition during the 1969 to 1974 period was atypical since it was dominated by the outstanding 1962 and 1963 year classes which continued to contribute substantially at ages 6 and older.

## ABUNDANCE INDICES

## Commercial Catch Rates

Commerical fishery catch rates were calculated for the Canadian fishery based on representative trips (i.e., only those vessels which reported more than 1 mt from 5Zjm during 1994 and where cod, haddock and pollock comprised over $90 \%$ of the total catch). Catch rates for tonnage classes 2 and 3 otter trawlers and longliners have generally increased since 1993 to 2000 but have leveled out since then (Figure 10). Changes to regulations, gear modifications and varying fishing practices in recent years and other factors make comparison of annual catch rates difficult to interpret. As a result, commercial catch rates were not used as indices of relative abundance.

## Research Surveys

Surveys of Georges Bank have been conducted by DFO each year (February) since 1986 and by NMFS each fall (October) since 1963 and each spring (April) since 1968. All surveys used a stratified random design (Figures 11 and 12). For the NMFS surveys, two vessels have been employed and there was a change in the trawl door in 1985. Vessel and door type conversion factors (Table 12), derived experimentally from comparative fishing, have been applied to the survey results to make the series consistent. Additionally, two trawl nets were used on the NMFS spring survey, a modified Yankee 41 during 1973-81 and a Yankee 36 in other years, but no conversion factors are available for haddock (Forrester et al 1997).

The spatial distribution of catches for the most recent surveys was plotted to show the distribution in comparison to the average over the previous 5 year period (Figures 13, 14 and 15). The 2003 year class at age 0 in the NMFS fall survey was abundantly and widely distributed as has been previously observed for large year classes. At age 1, the DFO February
survey found this year class abundantly distributed on the northern edge, peak and southern flank while the NMFS spring survey found large catches on the southern flank. Very low catches of the 2001 and 2002 year classes where observed in all three surveys. In winter/spring, adults (ages $3+$ ) are usually more abundant on the Northern Edge but in 2004 adults were also found abundantly on the southern flank in the DFO February survey. A few months later, the NMFS spring survey observed them more widely spread out over the survey area than in the DFO survey, which is consistent with past years. In fall, adult haddock are more concentrated in the deeper waters along the slopes of the Northeast Peak and the Northern Edge, however, fall survey catches of adult haddock were unusually low in 2003, in comparison to the high catches in the spring surveys.

Age-specific, swept area abundance indices show that the three surveys are consistent and track year class strengths well (Tables 13, 14 and 15; Figure 16). Some year effects are evident, however. For example, the low spring catches observed for both the 1997 DFO and NMFS surveys. All three surveys show the 2003 year class as the strongest in the series. The NMFS fall survey failed to catch many of the 2000 yearclass in 2003.

The indices for ages 3-8 survey biomass peaked during the early 1960s (Figure 17). After declining to a record low in the early 1970s, they peaked again in the late 1970s, though at a lower level, and again during the mid to late 1980s at about half the level of the 1970s peak. Biomass generally increased during the 1990s. The DFO and NMFS spring 2004 biomass remained near the highest level observed. The NMFS 2003 fall survey adult biomass dropped substantially from the previous year, when it was near the highest level reported for this survey.

Survey recruitment indices for ages 0 and 1 suggest that the 2003 year class is as abundant as the outstanding 1963 year class (Figure 18). The abundance of the 2000 year class is comparable to the good 1975 and 1978 year classes, with the 1998 year class being the third strongest since the 1978. The 1996 and the 1999 year classes were comparable to the moderate 1983, 1985, 1987 and 1992 year classes. These year classes were considerably smaller than the strong 1975 and 1978 year classes and the exceptional 1963 year classes. Survey results also suggest that the 2001 and 2002 year classes are relatively weak.

## GROWTH

Fishery weights at age (Table 11, Figure 8) for ages 2 and 3 are now generally higher than they were prior to the early 1990s. This increase reflects the change in gear selectivity which occurred around that time. Fishery weights in 2003 went down for all ages and all 2004 DFO survey weights except age 4 went down from 2003. There is a recent trend for older ages in both the fishery and DFO survey toward lower weights. Survey lengths at age also show decreases and are at or near their lower range (Table 16 and Figure 19). Average weight at age of haddock from the 1989, 1990 and 1991 year classes were higher than adjacent year classes in both the surveys and the commercial fisheries, giving the false impression of a declining trend in the years following. The method of calculation of the weights at age from the DFO survey, which were used for beginning of year population weights, was given in Gavaris and Van Eeckhaute (1998) and were derived from weights observed during the survey, weighted by population numbers at length and age. Fishery weights at age are derived from the sampled length at age and a length-weight relationship (Waiwood and Neilson 1985). In some cases, the mean weight at age in the catch is larger than the population mean weight at age at the beginning of the following year for the same cohort. This feature was mostly attributable to commercial fishery gear selectivity (Gavaris and Van Eeckhaute, 2000). However, some discrepancies in weights at age were more persistent and may be due to problems associated with the length-weight relationship and gutted-to-round weight conversion factors.

## HARVEST STRATEGY

The Transboundary Management Guidance Committee has adopted a strategy to maintain a low to neutral risk of exceeding the fishing mortality limit reference, $\mathrm{F}_{\text {ref }}=0.26$. When stock conditions are poor, fishing mortality rates should be further reduced to promote rebuilding.

## ESTIMATION OF STOCK PARAMETERS

## Calibration of Virtual Population Analysis (VPA)

The adaptive framework, ADAPT, (Gavaris 1988) was used to calibrate the virtual population analysis with the research survey data. An investigation of model formulations and model assumptions was conducted by Gavaris and Van Eeckhaute (1998) They provide details for the established model formulation and objective function used in this assessment. Based on this formulation it was assumed that observation errors for the catch at age data were negligible. Observation errors for the abundance indices were assumed to be independent and identically distributed after taking natural logarithms of the values. The annual natural mortality rate, M , was assumed constant and equal to 0.2. Similar model assumptions and methods were applied to the updated information here. Minor differences in the handling of zero terminal catches for a year class were implemented as a refinement to the software to afford more flexibility. The population abundance for the 9+ age group was calculated but not calibrated to the indices. In the first quarter of the first year, the 9+ abundance calculation was based on the assumption that the fishing mortality for the $9+$ age group was equal to the population weighted fishing mortality for ages 4-8. In the first quarter of subsequent years, the 9+ abundance was calculated as the sum of the age 8 and age group 9+ abundances at the end of the last quarter of the previous year.

The VPA was based on quarterly catch at age, $C_{a, t}$, for ages $a=0,1,2 \ldots 8,9+$, and time $t=1969.0,1969.25,1969.5,1969.75,1970.0 \ldots 2003.75,2004.00$ where $t$ represents the beginning of the time interval during which the catch was taken. A catch of 0 was assumed for the $1^{\text {st }}$ quarter of 2004 and the population was calculated to the beginning of 2004.25. The VPA was calibrated to bottom trawl survey abundance indices, $I_{s, a, t}$, for
$s=$ DFO, ages $a=1,2,3 \ldots 8$, time $t=1986.16,1987.16 \ldots 2004.16$
$s=$ NMFS spring (Yankee 36), ages $a=1,2,3 . .8$, time $t=1969.29,1970.29,1971.29$, 1972.29, 1982.29, 1983.29...2004.25
$s=$ NMFS spring (Yankee 41), ages $a=1,2,3 \ldots 8$, time $t=1973.29,1974.29 \ldots 1981.29$
$s=$ NMFS fall, ages $a=0,1,2 \ldots 5$, time $t=1969.69,1970.69 \ldots 2003.69$
The NMFS spring survey in 2004 was designated as occurring at time 2004.25 instead of 2004.29. The NMFS fall survey captures young of the year and that information is included as 0 group, but older haddock appear less available during this season. Survey indices for older ages where catches were sparse and where there were frequent occurrences of zero catches were not included (e.g., NMFS fall survey ages 6 and older and ages greater than 8 in the NMFS spring and the DFO surveys). Zero observations for abundance indices were treated as missing data as the logarithm of zero is not defined. During years when discarding was high, survey information was used along with interviews to obtain estimates of the USA catch. This
lack of complete independence between catch and survey data does not influence population estimates but may deflate variance estimates marginally.

Statistical properties of estimators were determined using conditional non-parametric bootstrapping of model residuals (Efron and Tibshirani 1993,Gavaris and Van Eeckhaute 1998). Population abundance estimates had a relatively large potential bias at age 1, had a relative error of about $65 \%$ and a potential bias of over $10 \%$ while the relative error for other ages was between about $25 \%$ and $45 \%$ with a potential bias between $3 \%$ and $8 \%$ (Table 17). The relative bias on fishing mortality for ages 4 and older in 2003 was also small at about $3 \%$. While the trends in the three surveys are generally consistent, they exhibit high variability and the average magnitude of residuals was large relative to other assessments. Although several large residuals were apparent, these data points do not appear to have a substantial impact on estimates of current abundance (Figures 20-24). Some patterns in the residuals (by cohort and by age) suggest year class and/or year effects in the survey data.

## Retrospective Analysis

Retrospective analysis is used to detect a pattern of inconsistencies, where updates of previously estimated fishing mortality, biomass, and recruitment show a tendency to be predominantly higher or predominantly lower. This stock assessment model, however, does not exhibit a retrospective pattern. While recruitment estimates may sometimes change substantially when more data becomes available, e.g., the 1998 and 2000 year classes, successive estimates of year class abundance at age do not display any persistent tendency to be predominantly higher or lower (Figure 25). Similarly, retrospective analysis showed no persistent patterns in the estimates of adult biomass (ages 3-8) or fishing mortality (ages 4-8 weighted by population numbers) (Figure 26).

## STATE OF RESOURCE

The state of the resource was based on results from the calibrated age structured VPA. For each cohort, the terminal population abundance estimates from ADAPT were adjusted for bias estimated from the bootstrap, and used to construct the history of stock status (Tables 1819). This approach for bias adjustment, in the absence of an unbiased point estimator with optimal statistical properties, was considered preferable to using potentially biased point estimates (O'Boyle 1998). The weights at age from the DFO survey (Table 16) were used to calculate beginning of year population biomass (Table 20). A weight of 2.4 kg , which was midway between the age 6 and 8 weight for that cohort, was used for age 7 in 1995 as no data were available for that age group. The 1986-95 average weight at each age was used for 196985. Data to approximate the age composition of the catch from unit areas 5Zj and 5Zm were also available for the period between 1931 and 1955 in order to reconstruct an illustrative population analysis of eastern Georges Bank suitable for comparison of productivity.

Adult population biomass (ages 3+) during the late 1970s and early 1980s was about $40,000 \mathrm{mt}$, due to recruitment of the strong 1975 and 1978 year classes whose abundances were estimated at about 50 million each (Figure 27). However, biomass declined rapidly in the early 1980s as subsequent recruitment was poor and these two year classes were fished intensely at a young age. The biomass has steadily increased from near an historical low of about 9,000 mt in 1993 to about 76,000 mt ( $80 \%$ Confidence Interval: 69,500 mt - 112,000 mt, Figure 28) at the beginning of 2004. The recent increase has been due to generally improved recruitment and was enhanced by lower exploitation and by reduced capture of small fish in the fisheries. Biomass has been increasing and is the highest it has been in about 30 years. It is now well within the range of the 1931-1955 biomass.

Recruitment improved in the 1990s and the 2003 year class, estimated at 905 million at age 1 may be comparable to the outstanding 1963 year class (Figure 27). The 2000 year class ( 81 million at age 1) is estimated to be larger than the strong 1975 and 1978 year classes. The 1998 year class (28 million at age 1) is the third strongest since that of 1978. The 1996 and 1999 year classes were estimated to be about 13 million, comparable to the 1983, 1985 and 1987 year classes, which were the strongest 3 year classes over about a 20 year time span. Two recent year classes, 2001 and 2002, are weak, at about 4 and 2 million fish, respectively.

The estimate of the 2003 year class had high uncertainty. A robust regression technique (least-trimmed squares regression analysis (Rousseeuw 1984)) was applied to provide an alternative estimate of the 2003 year class. VPA recruitment (age-1) was regressed on observed survey numbers at age zero or one using combinations of NMFS spring and fall as well as DFO survey data. Results confirmed that this year class is exceptional but its magnitude, estimated at about 500 to 600 million fish depending on the choice of surveys, may be smaller than the bias adjusted VPA estimate ( 905 million fish).

Fishing mortality for fully recruited ages $4+$ fluctuated between 0.2 and 0.4 during the 1980s (Figure 29) and showed a marked increase between 1989 and 1993 to about 0.6, the highest observed, before declining to below the fishing mortality reference, $F_{\text {ref }}=0.26$, where it has remained since 1995 ( $\mathrm{F}_{2003}=0.16$ : 80\% Confidence Interval: $0.13-0.19$, Figure 28).

Reduced fishing mortality in recent years has resulted in increased survival of recruiting year classes. The number of haddock of the 1992 year class surviving to age 8 was about four times that of the equally abundant 1983 year class, and about the same as that of the 1975 or 1978 year classes, which were more than 3 times as abundant (Figure 30). Avoidance of small fish by the fishery has resulted in increased survivorship at age 3 of the 1998 year class in comparison to the 1978 year class which was twice as strong.

Gains in fishable biomass may be partitioned into those associated with somatic growth of haddock, which have previously recruited to the fishery, and those associated with new recruitment to the fishery (Rivard 1980). We used age 2 as the age of first recruitment to the fishery. This choice facilitated comparisons with historic stock productivity but may be less representative of the current fishery selectivity. Except for 1996 and 2003, since 1993 surplus production (biomass gains from growth and from recruitment, decremented by losses due to natural deaths) has exceeded the fishery harvest yield, resulting in net increase (Figure 31). Growth of fish is the dominant component of the biomass gain but recruitment accounts for significant portions when stronger year classes enter the population (Figure 32). Growth of the 2000 year class was not enough to offset the small biomass gain from the weak recruiting 2001 year class and losses due to fishing and natural mortality. As a result, fishable biomass decreased slightly in 2004.

## PRODUCTIVITY

Attributes like recruits per spawner, age structure and spatial distribution reflect possible fluctuations in the productive potential and can be used to qualify reference points and acceptable risk.

Stock-recruitment data indicates that the chance of a good year class is significantly enhanced for adult biomass above about 40,000 mt (Figure 33). Since 1969, only the 1975, 1978, 2000 and 2003 year classes have been above the average abundance of year classes observed during the period 1930-55. The recruits per adult biomass ratio was generally low during the 1980s (Figure 34). Except for the 2001 and 2002 year classes, which are lower, and the 2003, which is higher, the present recruits per adult biomass ratio appears comparable to
that of the 1931 to 1955 period, suggesting that higher recruitment might occur when the biomass is above $40,000 \mathrm{t}$.

Since 1995, in both absolute numbers and percent composition, a broad representation of age groups is now apparent, reflecting improving recruitment and lower exploitation, particularly at younger ages (Figure 35).

The spatial distribution patterns observed during the most recent bottom trawl surveys were similar to the average patterns over the previous five years. However, consistent with the pattern observed for previous large year classes, the exceptional 2003 year class at age 0 was distributed more widely throughout the survey area.

Observed DFO survey average weights at length, used to reflect condition, show a slight decrease in recent years for larger haddock ( $68-73 \mathrm{~cm}$ ) although no trend is apparent for smaller haddock (50-53 cm) (Figure 36).

In summary, productivity has increased since the 1980s due to improved production of recruits per spawner and increases in the number of larger and older fish in the population.

## OUTLOOK

The outlook is provided in terms of the possible consequences for alternative catch quotas in 2005 with respect to the harvest reference points. Uncertainty about standing stock generates uncertainty in forecast results. This uncertainty is expressed in the outlook as the risk of exceeding $F_{\text {ref }}=0.26$.

Stock size estimates at the beginning of the second quarter in 2004 were used to start the forecasts. Abundances of the 2004 and 2005 year classes were assumed to be 20 million at age 0 . For each forecast, partial recruitment to the fishery for ages 1,2 and 3 and fishery weights at age were set to their averages during 1999-2003. Population weights at age were set to their observed 2004 values from the DFO survey (Table 21). It was also assumed that the total eastern Georges Bank total allowable catch (TAC) of 15,000 mt was caught in 2004. Natural mortality was assumed to be 0.2.

Given these forecast assumptions, a combined Canada/USA catch of 26,000 mt in 2005 would result in a neutral risk (50\%) that fishing mortality in 2005 will exceed $F_{\text {ref. }}$. A lower catch of $23,000 \mathrm{mt}$ would produce a low risk ( $25 \%$ ) that the fishing mortality in 2005 will exceed $\mathrm{F}_{\text {ref }}$ (Figure 37). Results indicate that the 2000 year class (age 5) would comprise the highest proportion of the total 2005 yield, accounting for about $47 \%$ of the catch at the $26,000 \mathrm{mt}$ level. The 2003 year class would account for the second highest proportion at $27 \%$ of the catch biomass.

The accuracy of the risk calculations depend on model assumptions and data. Though these assumptions were judged to be reasonable, other factors not considered could generate additional uncertainty. In particular, these calculations do not include uncertainty due to variations in weight at age, partial recruitment to the fishery, natural mortality, systematic errors in data reporting or the possibility that the model may not reflect the stock dynamics closely enough. In this context, the risk profiles show the range of uncertainties and the consequences of alternative catch quotas.

Medium term forecasts were also conducted. In these forecasts, it was assumed that the stock was exploited at a constant fishing mortality rate of 0.26 . Recruitment was assumed to equal either its most recent 10-year average ( 20 million, excluding the 2003 year class) or the
average recruitment which occurred during the period 1931 - 1955 (40 million) when the stock was at a more productive level. Results indicated that catches and biomass would increase substantially (Tables 22 and 23) under either recruitment scenario. The difference in projected total biomass, adult biomass and yield using the two recruitment assumptions was minimal.

## SPECIAL CONSIDERATIONS

Consistent management by Canada and the USA is required to ensure that conservation objectives are not compromised.

The outstanding 2003 year class is likely to dominate the catch during 2006 to 2008. If this year class is as abundant as estimated (about 900 million fish), fishery yields at $F_{\text {ref }}$ will increase by an order of magnitude starting in 2006. It is important to note that the estimate of the 2003 year class has high uncertainty. Alternative analyses support the conclusion that this year class is exceptional but suggest its magnitude may be somewhat smaller than the VPA estimate. This note of caution should be considered when evaluating the projection risk analysis. Measures should be taken to avoid wastage of this year class due to discarding.

Cod and haddock are often caught together in groundfish fisheries, although their catchabilities to the fisheries differ and they are not necessarily caught in proportion to their relative abundance. With current fishing practices and catch ratios, the achievement of rebuilding objectives for cod may constrain the harvesting of haddock. Modifications to fishing gear and practices, with enhanced monitoring, may mitigate these concerns.

## ACKNOWLEDGEMENTS

G. Donaldson, E. Williams and the Scotia Fundy Mobile Gear Fishermen's Association provided samples from the Canadian fishery. We thank members of the fishing industry who spent time to discuss their experiences in the fishery. We also thank Stratis Gavaris and William Overholtz for providing valuable comments on the draft manuscript.

[^0]Table 2. Regulatory measures implemented for the $5 Z$ and $5 Z \mathrm{jm}$ fishery management units by the USA and Canada, respectively, from 1977, when jurisdiction was extended to 200 miles for coastal states, to the present.

|  | USA | Canada |
| :---: | :---: | :---: |
| 1977-82 | Mesh size of 5 1/8" (140 mm), seasonal spawning closures, quotas and trip limits. |  |
| 1982-85 | All catch controls eliminated, retained closed area and mesh size regulations, implemented minimum landings size ( 43 cm ). | First 5Ze assessment in 1983. |
| 1984 Oct. | Implementation of the 'Hague' line . |  |
| 1985 | $51 / 2 "$ mesh size, Areas 1 and 2 closed February-May. |  |
| 1989 |  | Combined cod-haddock-pollock quota for 4X-5Zc |
| 1990 |  | 5Zjm adopted as management unit. <br> For MG < 65 ft . - trip limits with a $30 \%$ by-catch of haddock to a maximum of 8 trips of $35,000 \mathrm{lbs}$ per trip between June 1 and Oct. 31 and 130 mm square mesh required. <br> Fixed gear required to use large hooks until June |
| 1991 | Established overfishing definitions for haddock. | MG < 65 ft similar to 1990 but mesh size increased to 145 mm diamond. |
| 1992 |  | Introduction of ITQs and dockside monitoring. Total allowable catch $(T A C)=5000 \mathrm{mt}$. |
| 1993 | Area 2 closure in effect from Jan 1-June30. | OT fishery permitted to operate in Jan. and Feb. Increase in use square mesh. TAC $=5000 \mathrm{mt}$. |
| 1994 | Jan.: Expanded Area 2 closure to include June and increased extent of area. <br> Area 1 closure not in effect. <br> 500 lb trip limit. <br> Catch data obtained from mandatory log books combined with dealer reports (replaces interview system). <br> May: 6" mesh restriction. <br> Dec.: Area 1,2 closed year-round. | Spawning closure extended to Jan. 1 to May 31. Fixed gear vessels must choose between $5 Z$ or 4 X for the period of June to September. <br> Small fish protocol. <br> Increased at sea monitoring. <br> OT > 65 could not begin fishng until July 1. <br> Predominantly square mesh by end of year. $\text { TAC = } 3000 \mathrm{mt} .$ |
| 1995 |  | All OT vessels using square mesh. Fixed gear vessels with a history since 1990 of 25 t or more for 3 years of cod, haddock pollock, hake or cusk combined can participate in 5Z fishery. ITQ vessel require at least 2 t of cod and 8 t of haddock quota to fish Georges. TAC $=2500 \mathrm{mt}$. |
| 1996 | July: Additional Days-at-Sea restrictions, trip limit raised to 1000 lbs. | Fixed gear history requirement dropped. TAC $=4500$ mt . |
| 1997 | May: Additional scheduled Days-at-sea restrictions. September: Trip limit raised to $1000 \mathrm{lbs} /$ day, maximum of $10,000 \mathrm{lbs} /$ trip. | Vessels over 65 ft operated on enterprise allocations, otter trawlers under 65 ft on individual quotas, fixed gear vessels $45-65 \mathrm{ft}$ on self-administered individual quotas and fixed gear vessels under 45 ft on community quotas administered by local boards. TAC $=3200 \mathrm{mt}$. |
| 1998 | Sept. 1: Trip limit raised to $3000 \mathrm{lbs} / \mathrm{day}$, maximum of 30,000 lbs/trip. | Fixed gear vessels $45-65 \mathrm{ft}$ operated on individual quotas. TAC $=3900 \mathrm{mt}$. |
| 1999 | May 1: Trip limit 2,000 lbs/day, max. 20,000 lbs/trip. Square mesh size increased to $6.5^{\prime \prime}$ (diamond is 6 "). June 15: Scallop exemption fishery in Closed Area II. Nov. 5: Trip limit 5,000 lbs/day, max. 50,000 lbs/trip. | TAC= 3900 mt . |
| 2000 | October: Daily trip limit suspended to April 2001but retained max. trip limit of $50,000 \mathrm{lbs} /$ trip. | TAC $=5400 \mathrm{mt}$. |
| 2001-2002 | Day and trip limit adjustments. Daily trip limit suspended July 5, 2002. | TAC= 6989 mt. and 6740 mt. for 2001 and 2002 respectiviely. |
| 2002-2003 | $30,000-50,000 \mathrm{lb} /$ trip limit. <br> Trip limit suspended in Oct. 2003. | TAC= 8431 for 2003 mt . |
| 2004 | May 1, day and trip limits removed. | No changes. |

Table 7. USA landings of haddock in 2003 by quarter and market category from unit areas 5Zjm and NMFS sampling intensity for lengths and ages.

| Market <br> category | Large | Scrod | Unclassified | Total |
| :--- | ---: | ---: | ---: | ---: |
|  |  |  |  |  |
|  |  |  |  |  |
| Quarter 1 | 82.91 | 96.23 | 0.49 | 179.63 |
| Quarter 2 | 496.49 | 538.43 | 5.69 | 1040.61 |
| Quarter 3 | 49.89 | 36.68 | 5.63 | 92.20 |
| Quarter 4 | 26.29 | 221.91 | 2.96 | 251.16 |
| Total | 655.58 | 893.25 | 14.77 | 1563.60 |

## Lengths per 100 mt (Number measured)

| Quarter 1 | $118.20(82.91)$ | $0(0)$ | N/A | $54.56(179.63)$ |
| :--- | ---: | ---: | ---: | ---: |
| Quarter 2 | $127.50(496.49)$ | $53.49(538.43)$ | $\mathrm{N} / \mathrm{A}$ | $88.51(1040.61)$ |
| Quarter 3 | $218.48(49.89)$ | $0(0)$ | $\mathrm{N} / \mathrm{A}$ | $118.22(92.20)$ |
| Quarter 4 | $426.02(26.29)$ | $42.81(221.91)$ | $\mathrm{N} / \mathrm{A}$ | $82.42(251.16)$ |
| Total | $145.21(655.58)$ | $42.88(893.25)$ | $\mathrm{N} / \mathrm{A}$ | $85.38(1563.60)$ |

Ages per 100 mt (Number aged)

| Quarter 1 | $38.60(32)$ |  | N/A | $17.81(32)$ |
| :--- | ---: | ---: | ---: | ---: |
| Quarter 2 | $34.44(171)$ | $13.74(74)$ | $\mathrm{N} / \mathrm{A}$ | $23.54(245)$ |
| Quarter 3 | $84.19(42)$ |  | $\mathrm{N} / \mathrm{A}$ | $45.55(42)$ |
| Quarter 4 | $95.09(25)$ | $11.72(26)$ | $\mathrm{N} / \mathrm{A}$ | $20.31(51)$ |
| Total | $41.18(270)$ | $11.20(100)$ | $\mathrm{N} / \mathrm{A}$ | $23.66(370)$ |

Table 14. Total swept area estimated abundance at age (numbers in 000's) of haddock for unit areas 5Zjm from NMFS spring surveys during 1968-2004. From 1973-81, a 41 Yankee trawl was used while a 36 Yankee trawl was used in other years. Conversion factors to adjust for changes in door type and survey vessel were applied.

| Year | Age Group |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 21. Risk projection input for haddock in unit areas 5Zjm for the 2005 fishery and projection input for the 2005 to 2008 fishery. A catch of $15,000 \mathrm{mt}$ in 2004 and $\mathrm{M}=$ 0.2 were assumed for the forecasts. Two projections were made, one using 20 million recruits for the 2004 to 2009 year classes, the other using 40 million.

## Appendix A

## Estimation of haddock discards from the Canadian scallop fishery for 1996 to 2003

Management measures established in 1996 prohibited the landing of groundfish (except monkfish) by the Canadian scallop fishery. No records of discards from this fishery are available. The only data available to estimate haddock discards is from a limited number of observed trips. The approach used to estimate discards was to prorate the observed haddock catch per unit of effort (CPUE) to the total effort by the fleet.

In 1994, 1995 and 1998 there were 8 monitored trips which were used to estimate discards for 1996 to 2000. These trips took place in January, March and June and were designated as occurring either in 5Zj or 5Zm (Table A1). The catch and effort data could be disaggregated to area and, since haddock show seasonal migrations and are not distributed homogenously thoughout the fishing area, it was considered appropriate to calculate haddock bycatch rates by area, although the data were far from satisfactory in their ability to discern area differences. As temporal coverage was limited to 3 months in the first half of the year, it was not possible to calculate the haddock CPUE on a monthly or quarterly basis. Also, the data precluded the calculation of yearly CPUE estimates so two, area specific CPUEs were calculated by dividing the sum of the haddock catches by the sum of the effort for each area from all observed trips. The resultant annual CPUEs for $5 Z \mathrm{j}$ and $5 Z \mathrm{~m}$ were used with annual area specific scallop fishery effort data (pers. com. Ginette Robert 2004) to estimate the annual total haddock bycatch for 1996 to 2000 (Table A2). Estimated bycatch rates for 5Zj were considerably higher than for 5 Zm but total haddock bycatch was very low and was in the range of 21 to 54 mt per year based on the calculations described above. Subsequent to the review of this data by the Transboundary Resource Assessment Committee it was noted that the reported haddock catch for monitored trips was only for observed tows while the effort was for the entire trip (generally about $80 \%$ of tows might be observed), therefore the discard estimates should be adjusted upward in future. Since set location is available, and trips may fish in both areas, the subsequent revisions will be done using detailed set by set information.

In response to a Fisheries Resource Conservation Council recommendation, a monitoring program was conducted by the Canadian offshore scallop industry in 2001 and 2002 to gather data on bycatches of yellowtail flounder and monkfish. Additionally, bycatches of cod, haddock and pollock were also documented. The haddock bycatch estimates from these trips were used to estimate haddock bycatch for 2001 to 2003. Twelve trips were observed which covered all months except January and October (Table A3). One trip was exclude from the analysis as no effort data were available for this trip. Although some area information was available for these trips, examination of the positional data showed that most of the effort occurred in or very close to 5Zj and, since the haddock bycatch from the observed trips was not available by area, area specific CPUE was not derived. The haddock bycatch from observed sets was prorated upward to account for all sets and the CPUE was calculated by quarter (Table A3). The resulting quarterly CPUEs (sum of haddock catches per quarter divided by sum of effort per quarter) were then applied to the total quarterly effort of the scallop fleet. Total haddock discards for 2001 to 2003 were estimated to be 50, 36 and 78 mt , respectively (Table A4).

The 7 to 9 mt of haddock bycatch, depending upon which method was used, estimated for May to December 2001 by Kenchington (2002), which pro-rates to 11.6 to 14.0 mt for the whole year, is substantially lower than the estimates reported here. The difference in bycatch is due to several factors. The Kenchington estimates use only the 2001 observed trips. The use of the additional data from the 3 trips observed in 2002 increases the average bycatch per trip by almost double. The quarter 1 catch rates were comparable to the quarter 4 catch rates which were substantially greater than quarters 2 and 3 (Table B3). Bycatch for quarter 1 is not
included in the Kenchington report and prorating using the average bycatch rate for May to December produces lower values than when prorating using the higher quarter 1 rate obtained from the 2002 observed trips. The Kenchington estimates were obtained by prorating using trip as the effort measure or they were prorated using the scallop landings. The results presented here were prorated using hours as the effort measure. The average total trip effort in hours for the observed trips was substantially less than the average for the unobserved trips. The May to December trips were about 30\% longer while the January to April trips were almost double. This difference in trip length results in the observed bycatch rate being applied to a substantially greater number of hours for the method presented here. A final factor is that the Kenchington estimate is for scallop management zone 'a' only while this estimate includes zone 'b' as well. Scallop fishing effort in zone 'b' in 2001 occurred from January to June and appears to be substantial (DFO 20002).

Table B4. Inter-reader ageing agreement matrix for the DFO hadock ager, L. Van Eeckhaute (LVE), and the NMFS haddock ager, Sandy Sutherland (SJS), using haddock ageing material from the 2003 DFO and NMFS spring surveys and the 2002 Canadian fishery.

2003 DFO Survey \& 2002 Canadian Fishery: SJS vs LVE

[^0]:    ${ }^{1} 1895 \mathrm{mt}$ excluded because of suspected area misreporting.

[^1]:    ${ }^{1}$ Total includes catches for tonnage classes which are not listed, only tonnage classes with substantial catches listed
    ${ }^{2}$ Catches of 26 t , 776 t , 1091t and 2 t for side otter trawlers and stern otter trawlers tonnage classes 2,3 and 5 respectively were excluded because of suspected area misreporting.

[^2]:    ${ }^{1}$ Average of $1999-2003$ for ages 1 to 3.
    ${ }^{2}$ Equal to 2004 from DFO survey.
    ${ }^{3}$ Average of 1999-2003 from fishery.
    ${ }^{4}$ 2006-2008 projection only.
    ${ }^{5}$ Risk projection only.
