#### Abstract

Cod, haddock and yellowtail flounder discards from the Canadian scallop fishery on Georges Bank were estimated for 1960 to 2004 from 9 observed trips in 1991, 1994, 1995 and 1998, 12 observed trips in 2001 and 2002 and 5 observed trips in 2004. Data were insufficient to determine spatial differences but temporal (quarterly) trends were detected for all three species. The analysis was split into 2 periods, 1996 to 2004 when landing of groundfish was not permitted and 1960 to 1995, when groundfish landings were allowed for this fishery. Three approaches were used to estimate discards. Ratios of groundfish discards to landed groundfish, scallop effort and landed scallop were determined from observed trips and applied to annual landed groundfish, scallop fishery effort and landed scallop for 1960 to 1995. For the period 1996 to 2004, a discard to scallop effort ratio was determined from available data and quarterly ratios incorporating a seasonal pattern were interpolated from these for periods when no observed trips were available. Resultant discard rates were then applied to the total quarterly effort of the scallop fleet. Discard rates were highest for yellowtail flounder and cod while those for haddock were substantially lower.

## RÉSUMÉ

Nous avons estimé, pour la période 1960-2004, les rejets de morue, d'aiglefin et de limande à queue jaune dans les pêches canadiennes des pétoncles sur le banc Georges à partir des données recueillies dans le cadre de 9 sorties assujetties à observation en 1991, 1994, 1995 et 1998, de 12 telles sorties en 2001 et 2002 et de 5 autres en 2004. L'insuffisance des données n'a pas permis d'établir si les rejets variaient en fonction du lieu, mais des tendances temporelles (trimestre) ont été dégagées pour les trois espèces. L'analyse est divisée en deux périodes : 1996-2004, lorsqu'il était interdit de débarquer du poisson de fond capturé dans le cadre de la pêche des pétoncles, et 1960-1995, lorsque cela était permis. Nous avons utilisé trois facteurs, que nous avons établis à partir des données sur les sorties assujetties à observation puis appliqués aux débarquements annuels de poisson de fond, à l'effort de pêche des pétoncles et aux débarquements de pétoncles de 1960 à 1995, pour estimer les rejets: la proportion de rejets de poisson de fond par rapport aux débarquements de poisson de fond, l'effort de pêche des pétoncles et les débarquements de pétoncles. Pour la période 1996-2004, nous avons établi les proportions de rejets par rapport à l'effort de pêche des pétoncles à partir des données disponibles, puis nous avons interpolé les proportions trimestrielles incorporant une tendance saisonnière à partir de celles-ci pour les périodes pour lesquelles aucune sortie n'a été assujettie à observation. Nous avons ensuite appliqué les taux de rejet ainsi obtenus à l'effort total trimestriel de la flottille de pétoncliers. La morue et la limande à queue jaune ont connu les taux de rejet les plus élevés, alors que le taux était nettement moins élevé pour l'aiglefin.

## INTRODUCTION

The Canadian scallop fishery on Georges Bank is considered one of the principal sources of groundfish discards. Discards due to the Canadian scallop fishery have not previously been included in assessments of eastern Georges Bank cod and haddock or of Georges Bank yellowtail flounder. Results from at-sea observer monitoring in 20012002, indicated discards of cod, haddock and yellowtail flounder were considerable relative to current landings. To conduct a meaningful assessment of groundfish stock status, the inclusion of discards as part of the total removals must be consistent over the entire time series. Discards cannot be included in some years and left out in others. The purpose of this paper was to estimate the discards of cod, haddock and yellowtail flounder from the Canadian scallop fishery on Georges Bank for 1960-2004.

Prior to 1996, landing of groundfish by-catch by the Canadian scallop fishery on Georges Bank was permitted. However, it is generally acknowledged that all the groundfish by-catch was not landed. To account for the total by-catch, it is necessary therefore to augment the landings by the scallop fishery with the discarded amounts of by-catch. Management measures established in 1996 prohibited the landing of groundfish (except monkfish) by the Canadian scallop fishery. All by-catch of cod, haddock and yellowtail flounder was therefore discarded. Discards, whether pre or post 1996, were not recorded in the scallop fishery statistics.

Discards can be estimated from information collected by at sea observer deployments. Few scallop fishery trips have had observer coverage (Table 1). Nine trips conducted in 1991, 1994, 1995 and 1998 were monitored (Figure 1). In response to a Fisheries Resource Conservation Council recommendation, a monitoring program was conducted by the Canadian offshore scallop industry in 2001 and 2002 to gather data on bycatches. Twelve trips were observed which covered all months except January and October (Figure 2). Starting in August 2004, routine observer deployment on vessels participating in the Canadian scallop fishery on Georges Bank was initiated. Five trips were observed in 2004 (Figure 3).

## Data and Methods

Incidental catch of groundfish in the Georges Bank scallop fishery will be referred to as "by-catch". By-catch may be landed. "Landed" refers only to that portion of the catch that is recorded in the fishery statistics records. Any by-catch that is not landed will be designated as "discards". Unless otherwise specified, the terms discard and landed are used to refer to the by-catch species of interest.

Three approaches to estimating discards of by-catch species in the scallop fisheries on Georges Bank were considered. All three approaches involve pro-rating observed discards by a total to observed ratio of some other quantity.

Approach A: discard / landed = observed discard / observed landed
giving discard = observed discard (landed / observed landed)
Approach B: discard / scallop effort = observed discard / observed scallop effort giving discard = observed discard (scallop effort / observed scallop effort)

Approach C: discard / landed scallop = observed discard / observed landed scallop
giving discard = observed discard (landed scallop / observed landed scallop)
Approach A is dependent on the assumption that discarding practices, i.e. the (discard / landed) ratio for observed scallop fishing, is representative of discarding practices for the scallop fishery. Approach B is dependent on the assumption that the by-catch population density, i.e. the (discard+landed / scallop effort) ratio for observed scallop fishing, is representative of that for the scallop fishery as well as on the assumption that discarding practices are representative. Approach C is dependent on the assumption that the relative population density of the by-catch species to the population density of scallop, i.e. the (discard+landed / scallop discard+landed) ratio for observed scallop fishing, is representative of that for the scallop fishery as well as on the assumption that discarding practices are representative. Further, because we only have information on the landed scallop catch, and some of the scallop catch is culled, this approach also depends on the assumption that discarding practices for scallop during observed scallop fishing is representative of that for the scallop fishery.

When sampling intensity is high and a large proportion of the scallop fishing is observed, all three approaches may give reliable results. The variability of the respective ratios used in approaches A, B and C influences how much observed sampling is required to obtain a representative view of the fishery. Population density generally varies by location and over seasons and years, while discarding practices may be more stable. Approach C is sensitive to variation in the population density of the by-catch species, to variation in the population density of scallop and to variation in discarding practices for scallop. Approach $B$ is sensitive to variation in the population density of the by-catch species. Approach A is only sensitive to variation in discarding practices for the by-catch species. However, Approach A can only be applied in situations where landing of the bycatch species is permitted. When there are no landings of the by-catch species or when landings are very low, only Approaches B or C can be considered. It can be postulated therefore, that, when the requisite information is available, Approach B should be favoured over Approach C and that Approach A might be favoured over both Approaches B and C. These considerations are particularly important when the sampling intensity is low and only a small proportion of the scallop fishing is observed, as the observed ratios used for pro-rating need to be applicable over broader spatial and temporal domains.

The analysis was done separately for two periods. The period 1996-2004, when landing of cod, haddock and yellowtail flounder was not permitted, was considered first because there was higher observer coverage. The period 1960-1995, when landing of cod, haddock and yellowtail flounder was permitted, is based on very limited observer coverage.

## Results and Conclusions

Discard Estimates for 1996 to 2004
Since landing of cod, haddock and yellowtail flounder was not permitted during this period, Approach B was applied to estimate discards. For this approach the observed trips for 1995, 1998, 2001, 2002 and 2004 were used to evaluate the discard to scallop effort ratio. The 1995 trips were included to permit interpolation for 1996 and 1997, as described below. To make 1995 comparable to trips where landing was not permitted, the sum of observed discards and kept was used as the by-catch.

Effort refers to hours towed, with usually 2 dredges being towed at the same time. As there is no adjustment for amount of gear in either number of dredges or size of dredges, it is assumed that the amount of gear used on observed trips is representative of the amount of gear used in typical operations. Effort information may be obtained from observer records or from fishery statistics. Since the fleet effort must be obtained from fishery statistics, it was considered preferable to use the effort from fishery statistics for the observed trips as well, to ensure consistency. However, this was not always possible and observed effort was derived for those cases.

Several observed trips for 1995 and 1998 were industry initiatives to evaluate modifications to standard scallop gear. When modified gear was used, it was usually towed along with the standard dredge as a control. In these instances, only catch from the standard scallop dredge configuration was used. The corresponding effort data could not be obtained from fishery statistics. For these trips the effort was obtained from observer records. In the instances where modified gear was used, the observed effort hours were halved to be equivalent to a standard industry tow where two dredges are usually towed together. As a check on the equivalency of the observed effort and fishery statistics effort, for a few trips where it was possible, the observed effort was pro-rated to the entire trip. The pro-rated effort compared favourably with the fishery statistics effort, 143 versus 143 for trip T1995-1, 128 versus 127 hours for trip T1995-3 and 141 versus 132 for trip T1998-1. Trip effort for the 2001, 2002 and 2004 observed trips was obtained from fishery statistics (pers. com. Dr. Ginette Robert, DFO).

The fishery statistics effort represents the hours fished for the entire observed trip. It is necessary therefore to prorate the observed discards to the discards for the entire observed trip. For trips in 1991-1998, observed effort hours were recorded. For these trips the proration factor was the ratio of observed to trip effort hours. For trips in 2001 and later, observed effort hours were not recorded. In the absence of effort hours, proration would preferably be done using the ratio of total tows to observed tows, but observer data was not recorded by tow either. For trips in 2001 and later, observers were instructed to group tows into "sets" of roughly 3 hours or more during which several tows were usually carried out. All catch data was recorded by "set". The number of dredges towed during a "set" was also recorded, but number of tows was not. The total discards for the trip was obtained by prorating the observed discards by the ratio of total number of dredges to observed number of dredges recorded for the trip. This was considered more accurate than using the ratio of total sets to observed "sets" since the number of tows and dredges in a set varied considerably.

Area specific effort from fishery statistics usually corresponded with the area designations by observers. However one observed trip, T2001-3, showed that sets had occurred in both unit areas 5Zj and 5Zm whereas effort from fishery statistics was supplied for unit area 5Zj only. Total effort for this trip was split between the two unit areas according to the number of dredges towed in each area from observer records.

Both temporal and spatial patterns in discard rates (sum of discards per quarter divided by sum of effort per quarter) might be expected, but there were not enough observed trips in 2001 and 2002 to calculate discard rates for each quarter and area as 5 Zm had observed trips only in April, June, July and August (Figure 2). Trips observed between 1991 to 1998 were also not suitable for investigating spatial patterns (Figure 1). Available data therefore, do not support any unit area patterns in discard rates for cod, haddock and yellowtail flounder (Fig. 4). There appeared to be temporal patterns for all 3
species. A tendency for higher discard rates of yellowtail flounder in quarter 2 and lower discard rates in quarter 4 were evident (Fig. 4). Cod and haddock exhibited similar patterns with higher rates occurring in quarters 1 and 4 and reduced rates in quarters 2 and 3. The cod and haddock spawning aggregations that occur on the bank in winter and spring coincide with the higher catch rates at this time of the year. While the dispersion of observations was great, these results were generally consistent with seasonal patterns of discard rates for 2004 and of landings per unit of effort (trip) observed during 1986-1995 (Figure 5). The landings patterns were very similar for yellowtail flounder but were somewhat different for haddock in quarter 4 and cod in quarter 2, although more similar to the pattern observed for cod in 5Zj alone (Figure 4). The discard rates from observed trips in 2001-2002 and in 2004 were aggregated to obtain seasonal factors (Figure 6). The proration was conducted using discard rate by quarters (Table 2). Trip T2002-3 from April 2002 was pooled with the other trips in the second quarter of 2001 to increase sample size.

Quarterly discard rates for periods when no observed trips were available were derived by interpolation and application of a seasonal pattern (Figure 7). To estimate discards for year 1996 and later, the quarterly discard rates were applied to the total quarterly effort of the scallop fleet (Table 3).

## Discard Estimates for 1960-1995

For this period when landings of cod, haddock and yellowtail flounder were allowed, Approach A which uses the ratio of discards to landings might have been preferred. However, the number of observed trips in this period was very limited and the ratios subject to the influence of anomalous outliers. Therefore results from all three approaches were compared and the results from the approach that gave the most reasonable values were used as the discard estimates.

The observed kept amount appears to include fish that were retained but not subsequently sold and recorded in the fishery statistics ("prorated kept" versus "landed" (Table 4)). This may reflect the practice of using "crew shares" as partial compensation or in the case of yellowtail flounder reporting it as another species. The zero yellowtail flounder landings reported for trip T1995-4 when 792 kg were observed kept (Table 1) is likely a result of reporting all the flounder caught for that trip as winter flounder. This trip was not used for calculating discard rates for yellowtail flounder. Assuming that the observed kept for trips T1994-1 and T1995-3 were landed, the observed kept from the other trips, which did not report any landed cod, haddock or yellowtail flounder, was prorated to the trip and added to the discards to derive an overall ratio of discard to landed, excluding trip T1995-4 for yellowtail flounder (Table 4). The resulting discard to landed ratio for yellowtail flounder was 3.74 (i.e. ( $7.484 \mathrm{mt}+0.138 \mathrm{mt}$ ) /2.038 mt). Similarly for cod and haddock, the discard to landed ratios were 0.681 for cod and 4.582 for haddock.

To obtain the discard to effort ratio needed for Approach B, the sum of the prorated kept for trips which did not report any landed by-catch were added to the sum of prorated discards, (excluding trip T1995-4 for yellowtail flounder), and divided by the sum of effort (Table 4). The resulting discard rate was $6.873 \mathrm{~kg} / \mathrm{h}$ (i.e. ( $7.484 \mathrm{mt}+0.138 \mathrm{mt}$ ) /1109 hr) for yellowtail flounder, $0.978 \mathrm{~kg} / \mathrm{h}$ for cod and $1.774 \mathrm{~kg} / \mathrm{h}$ for haddock (Table 4). These by-catch rates are within the range of the observed quarterly discard rates in 2001-2004 for yellowtail flounder and haddock but low for cod.

Finally, the discard to landed scallop ratio needed for Approach C was derived in a similar manner, i.e. sum of prorated discards plus prorated kept for non-reporting trips divided by the scallop landings. The resulting discard to landed scallop ratio was 0.0115 (i.e. $(7.484 \mathrm{mt}+0.138 \mathrm{mt}) / 660.384 \mathrm{mt}$ ) for yellowtail flounder, 0.0019 for cod and 0.0034 for haddock (Table 4). In comparison to the haddock ratio, the cod ratio seems low when contrasted with the 2001-2004 trend.

Resulting discards for 1960-1995 using each of the three approaches are summarized in Table 5 along with the discard estimates for 1996-2004. Scallop fishery effort was not available prior to 1972 and groundfish landings from the scallop fishery were unavailable prior to 1968 so not all approaches could be compared for all years. The discard estimates based on the discard to landed ratio do not appear consistent with the amount of effort and almost certainly underestimated the discard amounts. The discard estimates based on discard to effort ratio and discard to landed scallop ratio are fairly comparable. The landed scallop proration appears somewhat susceptible to variation in scallop abundance. For example, when effort remained high and yellowtail abundance was thought not to be changing much, estimated discards vary more than expected. Estimated discards also do not follow known abundance trends of by-catch species, due, no doubt, to the paucity of observer data used to calculate discard ratios.

In conclusion, the effort proration results appear most reasonable of the three approaches and were used in the stock assessments for the three species for 1972 to 1995. When scallop effort was unavailable, i.e. prior to 1972, the proration using scallop landings appears to be the next most reliable estimation. The proration methodology was reviewed during the framework review of the Georges Bank yellowtail flounder assessment in 2005 and was deemed acceptable.

Figure 1. Geographic distribution of Georges Bank scallop fishery trips which had observer coverage in 1991, 1994, 1995 and 1998. These were often industry initiated trips to evaluate modifications to standard scallop gear. The dates refer to the first and last day of scallop fishing.

Figure 2. Geographic distribution of scallop fishery trips monitored as part of a Canadian Georges Bank offshore scallop industry program to gather data on by-catches of selected groundfish in 2001 and 2002. The dates refer to the first and last day of scallop fishing and the landed date. The trip landed Sept. 24, 2001 was excluded from the analysis as effort data was unavailable.

Figure 3. Geographic distribution of Georges Bank scallop fishery trips monitored as part of routine observer deployment initiated in August 2004. The dates refer to the first and last day of scallop fishing and the landed date.

Figure 4. Quarterly discard rates ( $\forall 2 \mathrm{SE}$ ) for yellowtail flounder, cod and haddock from 12 observed Canadian scallop fishery trips on Georges Bank in 2001 and 2002.

Figure 5. Georges Bank scallop fishery quarterly by-catch trends in metric tonnes (mt) per trip by year from reported landings for 1986 to 1995 . Only trips that reported landings for the by-catch species were used.

Figure 6. Quarterly discard rate patterns for yellowtail flounder, cod and haddock from observed trips in 2001-2002 and 2004 were averaged to derive seasonal factors.

Figure 7. Quarterly discard rates from observed and interpolated values for yellowtail flounder, cod and haddock for 1996 to 2004.

[^0]:    ${ }^{1}$ April 2002 trip pooled with quarter 2 trips in 2001 to increase sample size.
