#### Abstract

The total catch of eastern Georges Bank (EGB) haddock in 2006 was $12,642 \mathrm{mt}$ under a combined Canada/USA quota of 22,000 mt. The 2006 Canadian catch decreased from 14,536 in 2005 to $12,051 \mathrm{mt}$ while the USA catch increased slightly from 569 mt in 2005 to 591 mt . Estimated discards from the Canadian scallop fishery were 67 mt and were 146 mt from the USA groundfish fishery. EGB haddock catches fluctuated about 5,000 mt during 1985-1990. Under restrictive management measures, combined Canada/USA catches declined from over $6,500 \mathrm{mt}$ in 1991 to a low of about 2,200 mt in 1995, averaged about 3,600 mt during 19961999 and have increased since then.

Adult population biomass (ages 3+) has steadily increased from near an historical low of $8,500 \mathrm{mt}$ in 1993 to $69,500 \mathrm{mt}$ in 2003. Adult biomass subsequently decreased to about $46,900 \mathrm{mt}$ at the beginning of 2005 but increased to $145,300 \mathrm{mt}$ in 2007, higher than the 19311955 maximum of about $90,000 \mathrm{mt}$. The exceptional 2003 year class, estimated at 321.7 million age-1 fish, is the largest observed in the assessment time series (1931-1955 and 1969-2005). The 2001, 2002 and 2004 year classes, at less than 8 million, are below the recent 10 year average of 18 million fish while the 2005 year class, at 30.5 million, is above the average. Initial estimates of the 2006 year class suggest that it is about the size of the 2004 year class. Fishing mortality (ages $4+$ ) was below $\mathrm{F}_{\text {ref }}=0.26$ during 1995 to 2004. The failure of the 2003 year class to recruit as expected to the 2005 and 2006 fishery resulted in fishing mortality in 2005 and 2006 exceeding $F_{\text {ref }}\left(F_{2006}=0.36\right)$. With expanded age structure, broad spatial distribution and generally higher recruit per spawner ratio, resource productivity is high, negatively impacted only by recent reductions in fish weight at age.

Assuming a 2007 catch equal to the $19,000 \mathrm{mt}$ total quota, a combined Canada/USA catch of $26,700 \mathrm{mt}$ in 2008 would result in a neutral risk (50\%) that the fishing mortality rate in 2008 will exceed $F_{\text {ref }}=0.26$. A catch of $23,000 \mathrm{mt}$ would result in a low risk ( $25 \%$ ) that the fishing mortality rate in 2008 will exceed $F_{\text {ref }}$. However, there is high uncertainty in the partial recruitment estimated for the 2003 year class. Using the observed range of partial recruitment at fishery weight during 1995 to 2006, the 2008 projected catch could vary from $17,000 \mathrm{mt}$ to $31,000 \mathrm{mt}$.

The failure of the 2003 year class to contribute as expected to the fishery resulted in more of the 2000 and older year classes being caught in 2006 than had been projected from the 2005 assessment. Slow growth of the 2003 cohort will continue to impact the fishery. If the total allowable catch in 2007 is caught, fishing mortality will, again, be higher than $F_{\text {ref }}$ on the fully recruited ages ( $F_{5+}=0.33$ ) because the 2007 age 4 fishery partial recruitment is now estimated at 0.2 compared to 0.3 from the 2006 assessment.

## RÉSUMÉ

Les prises totales d'aiglefin dans l'est du banc Georges en 2006 se sont chiffrées à 12642 tm, par rapport à un TAC combiné Canada-É. U. de 22000 tm . Les prises canadiennes ont diminué, passant de 14536 tm en 2005 à 12051 tm en 2006, tandis que celles des États Unis ont légèrement augmenté, passant de 569 tm en 2005 à 591 tm en 2006. Les rejets en provenance de la pêche du pétoncle au Canada et de la pêche du poisson de fond aux ÉtatsUnis ont été estimés à 67 tm et 146 tm , respectivement. Les fluctuations des prises d'aiglefin dans l'est du banc Georges ont été d'environ 5000 tm au cours de la période 1985 1990. Des mesures de gestion strictes ont fait baisser les prises combinées du Canada et des États-Unis, qui, après avoir dépassé 6500 tm en 1991, sont tombées à un seuil d'environ 2200 tm en 1995. Ces prises se sont ensuite situées en moyenne à 3600 tm de 1996 à 1999 et elles ont augmenté depuis.

La biomasse de la population d'adultes (âges $3+$ ) a constamment augmenté, passant du seuil quasi historique de 8500 tm qu'elle avait connu en 1993 à 69500 tm en 2003. Elle est tombée à 46900 tm au début de 2005, mais elle a ensuite augmenté à 145300 tm en 2007, dépassant d'environ 90000 tm la biomasse maximale des années 1931-1955. L'exceptionnelle classe d'âge de 2003, estimée à 321,7 millions de poissons d'âge-1, est la plus grande classe d'âge observée dans les séries chronologiques des évaluations (1931-1955 et 1969-2005). En revanche, les classes d'âge de 2001, 2002 et 2004, chiffrées à moins de 8 millions de poissons, se situent sous la moyenne des 10 dernières années, soit 18 millions de poissons, tandis que la classe d'âge de 2005, avec un effectif de 30,5 millions de poissons, est supérieure à la moyenne. Les premières estimations de la classe d'âge de 2006 portent à croire que son effectif équivaut à peu près à celui de la classe d'âge de 2004. La mortalité par pêche (parmi les âges $4+$ ) a été inférieure à $F_{\text {réf. }}=0,26$ de 1995 à 2004. Le recrutement attendu de la classe d'âge de 2003 à la pêche de 2005 et de 2006 ne s'étant pas produit, la mortalité par pêche de 2005 et de 2006 a été supérieure à $F_{\text {réf. }}\left(F_{2006}=0,36\right)$. En raison de l'élargissement de la structure d'âges, de la vaste distribution spatiale et du taux généralement plus haut de recrutement par reproducteur, la productivité de la ressource est haute, n'ayant subi comme effet négatif que les réductions récentes du poids du poisson selon l'âge.

En se fondant sur des prises hypothétiques en 2007 égales au quota de 19000 tm , des prises combinées Canada/États-Unis de 26700 tm en 2008 se traduiraient par un risque neutre ( 50 $\%$ ) que la mortalité par pêche dépasse $F_{\text {réf. }}=0,26$ en 2008. Des prises de 23000 tm aboutiraient à un faible risque ( $25 \%$ ) que la mortalité par pêche en 2008 dépasse $F_{\text {réf }}$ Toutefois, le recrutement partiel estimé pour la classe d'âge de 2003 est très incertain. D'après la fourchette des valeurs observées dans le recrutement partiel selon le poids de 1995 à 2006, les prises projetées pour 2008 pourraient varier entre 17000 tm et 31000 tm .

Étant donné que la classe d'âge de 2003 n'a pas contribué autant que prévu à la pêche, la quantité de poissons de la classe d'âge de 2000 et des plus vieilles classes d'âge qui a été capturée en 2006 a été supérieure à ce que prévoyait l'évaluation de 2005. La lente croissance de la cohorte de 2003 continuera de se répercuter sur la pêche. Si le total autorisé des captures est capturé en 2007, la mortalité par pêche sera de nouveau supérieure à $F_{\text {ref. }}$ parmi les âges pleinement recrutés ( $F_{5+}=0,33$ ), parce que le recrutement partiel à la pêche des poissons d'âge 4 en 2007 est maintenant estimé à 0,2 , alors que l'évaluation de 2006 le chiffrait à 0,3 .

## Introduction

For the purpose of developing a sharing proposal and consistent management by Canada and the USA, agreement was reached that the transboundary management unit for haddock would be limited to the eastern portion of Georges Bank (EGB) (DFO statistical unit areas $j$ and $m$ in NAFO sub-division 5Ze; USA statistical areas 551, 552, 561 and 562 in NAFO sub-division 5Ze; Figure 1; DFO 2002). This assessment applies the approach used by Van Eeckhaute and Brodziak (2006) to Canadian and USA fisheries information updated to 2006. Results from the Fisheries and Oceans Canada (DFO) survey, updated to 2007, and the USA National Marine Fisheries Service (NMFS) surveys in the spring, updated to 2007, and fall, updated to 2006, were incorporated.

## Fishery

## Commercial Catches

Haddock on Georges Bank have supported a commercial fishery since the early 1920s (Clark et al 1982). Catches from EGB during the 1930s to 1950s ranged between $15,000 \mathrm{mt}$ and $40,000 \mathrm{mt}$ (Figure 2), averaging about $25,000 \mathrm{mt}$ (Schuck 1951, R. Brown pers. com.). Records of catches by unit area for the early 1960s period have not been located. however, based on records for NAFO Subdivision 5Ze, catches from EGB probably attained record high levels of about 60,000 mt during the early 1960s. Catches in the late 1970s and early 1980s, ranging up to about $23,000 \mathrm{mt}$, were associated with good recruitment. Substantial quantities of small fish were discarded in those years (Overholtz et al 1983). Catches subsequently declined and fluctuated around 5,000 mt during the mid to late 1980s. Under restrictive management measures, combined Canada/USA catches declined from over $6,500 \mathrm{mt}$ in 1991 to a low of about 2,100 mt in 1995, fluctuated between about 3,000 mt and 4,000 mt until 1999 and increased to 15,112 mt in 2005 (Table 1, Figure 3). In 2006, the Canadian catch was 12,051 mt and the USA catch was 591 mt under quotas of $14,520 \mathrm{mt}$ for Canada and $7,480 \mathrm{mt}$ for the USA for a total combined catch of $12,642 \mathrm{mt}$ (combined quota was $22,000 \mathrm{mt}$ ). The landings for 2005 were updated from what was reported in the previous assessment but differences were minor.

Quotas are the principal means used to regulate the Canadian groundfish fisheries on Georges Bank. Canadian catches since 1995 were below the quota due to closure of some fleet sectors when the cod quotas were reached, except for the year 2000 when the catch of $5,402 \mathrm{mt}$ was slightly above the Canadian quota of $5,400 \mathrm{mt}$. Quota regulation requires effective monitoring of fishery catch. Weights of all Canadian landings in 2006 were monitored at dockside and at-sea observers monitored $31 \%$ by weight of the haddock landed in 2006. Discarding and misreporting of haddock by the groundfish fishery have been negligible since 1992.
Since 1994, the Canadian fishery for groundfish was usually not permitted from 1 January to 30 May. In 2005 and 2006, increasing haddock abundance led to an exploratory Canadian groundfish fishery. So as not to adversely affect the rebuilding of
cod on EGB, the exploratory winter fishery was closed (February 6 in 2006) when it was determined that cod were actively spawning, i.e. when $30 \%$ of cod were in the spawning or post-spawning stages.
In recent years, the Canadian fishery has been conducted primarily by vessels using otter trawls and longlines with some handlines and gillnets. Some elements of the management measures used on EGB are described in Table 2. Smaller vessels are allowed to fish the quota which has been allocated to the larger vessels under the Temporary Vessel Replacement Program (TVRP) and increasing amounts of this quota have been taken by the TVRP boats in recent years. In 2006, 95\% of the catch was taken by tonnage class 1, 2 and 3 (less than 150 tons) vessels (corresponding roughly to vessels less than 65 ft in overall length). Otter trawls took $84 \%$ of the haddock and longliners took 16\% (Table 3). The highest monthly catches in 2006 occurred during August followed by July and September (22\%, 20\% and 18\%, respectively) (Table 4, Figure 4). The winter fishery accounted for $13 \%$ of the landings.

Canadian landings until 1995 include those catches reported by the scallop fishery, but, since 1996, this fishery has been prohibited from landing haddock and this species was then discarded. Landings of haddock by the scallop fleet have been low (Table 3) with a maximum of 38 mt reported in 1987. Discards of haddock ranged between 29 and 186 mt since 1969 and were estimated at 67 mt in 2006 (Table 1) (Gavaris et al 2007). Details of discard calculations for the EGB scallop fishery for 1960 to 2005 can be found in Van Eeckhaute et al, 2005 and for 2006 in Van Eeckhaute and Gavaris, 2006.

Management measures for the USA fishery since 1994 have been effort based but, in 2004, quota management was introduced to regulate the USA groundfish fishery (Table 2). USA landings of EGB haddock in 2006 were derived from mandatory fishing vessel logbooks and dealer reports using the same procedures as for 1994-2005 (Wigley et al 1998). To estimate otter trawl discards, the discard to kept ratios from observed trips were used. Quarters 1 and 2 landings were combined and the quarter 2 discard to kept ratio was applied to estimate the combined quarters 1 and 2 discards. The quarter 3 ratio was applied to the quarter 3 discards. There were no landings, therefore no discards, reported for quarter 4.

USA catches, in 2006, of EGB haddock increased slightly from the previous year ( 569 mt ) and were 591 mt under a catch quota of $7,480 \mathrm{mt}$ (Table 1). As in 2005, the catch was constrained by the low cod quota with the fishery closing during the first half of the season when the cod quota was close to being reached. Quarterly USA landings in 2006 were: 47 mt (11\%), 393 mt (88\%), 5 mt (1\%) and 0 mt ( $0 \%$ ) for calendar quarters 1 to 4 respectively (Table 5).
USA discards from the otter trawl fishery increased from 57 mt in 2005 to 146 mt in 2006. Discards from this fleet had been relatively low in recent years due to high trip limits and larger trawl mesh size but, in 2006, $25 \%$ (by weight) of the haddock catch was discarded, an increase from 2004 and 2005 when discards accounted for $8 \%$ and $10 \%$, respectively, of the USA catch. The discards from the scallop fleet were not available but have been insignificant in the past.

Otter trawl gear accounted for the majority of the USA landings (414 mt). The contribution by other gear ( 31 mt ) was 7\%, higher than previous years since 1994, except for 2005, which was slightly higher at $9 \%$ (Table 6).

## Size and Age Composition

The size and age composition of haddock in the 2006 Canadian groundfish fishery was characterized using port and at-sea samples from all principal gears and seasons (quarters) (Table 7). For trips that were sampled by both at-sea observers and port samples, the length frequencies were combined to ensure that samples were used in a consistent manner. The size composition of haddock discards in the 2006 Canadian scallop fishery was characterized by quarter using length samples obtained from 11 observed scallop trips (Table 7). The 2006 DFO survey ages were applied to the first quarter length composition and fishery age samples for quarters 2 to 4 were applied to the corresponding length compositions for both the groundfish fishery and discards. Van Eeckhaute and Brodziak (2006) describe the methods used to characterize size and age composition in previous years.

The size composition of landings in the Canadian fisheries peaked at 52 to 55 cm for otter trawlers and longliners (Figure 5). The proportion of small haddock increased as the fishery progressed through 2006 (Figure 6). Gill-netters caught few haddock. The percentage of haddock below 43 cm increased from $1 \%$ in 2005 to $10 \%$ in 2006. The scallop dredge discards peaked at 40.5 cm .
USA landings of EGB haddock are divided into large and scrod market categories for sale purposes. Landings of large haddock totaled 132 mt and scrod haddock totaled 313 mt in 2006 (Table 8). Length samplings for USA EGB landings in 2006 were limited to quarters 2 and 3 with only 104 large fish and no scrod measured for quarter 3. Age sampling was similarly distributed with a total of 640 ages. Lengths were augmented from unit areas 522 (5Zh) and 525 ( $5 Z n$ ) for quarter 1 large and scrod and for quarter 2 scrod. Observer coverage decreased from a total of 44\% (226 mt) of USA haddock landings by weight from EGB in 2005 to $1.6 \%(7 \mathrm{mt})$ in 2006 during a total of 54 trips.

Samples of discards collected by at-sea observers were used to characterize the catch at length of the USA discards. Discard samples were available only for the otter trawl fleet. Scallop fleet discards were not available in time to include here but haddock discards from this fleet were insignificant. For the otter trawl fleet, only one fish measurement was taken in quarter 1 so quarters 1 and 2 were combined for the discards at age analysis. Quarter 3 had sufficient samples to obtain a length composition.
USA landings peaked at 54.5 cm and discards peaked around 30.5 to 36.5 cm with another much smaller mode at 52 cm (Figure 7). The reason for discarding of large haddock could not be explained. The high number of small discards was attributed to the use of diamond mesh and the use of chaffing gear.
Due to the low level of sampling and with the majority of the landings in quarter 2, an annual age-length key was applied to the USA landings and the resultant landings at age were assigned to quarter 2, where most of the landings occurred. For the otter trawl discards at age, quarter 2 and 3 age data were borrowed from USA port samples and

Canadian port and observer samples and from the NEFSC spring survey to cover smaller fish in quarter 2 and from the NEFSC autumn survey to cover smaller fish in quarter 3. The quarter 2 age-length key was applied to the combined discards for quarters 1 and 2, and a quarter 3 key to the quarter 3 discards at length.
Ages of survey and commercial-caught haddock were separately assigned by the DFO and the NMFS age readers, L. Van Eeckhaute and S. Sutherland, respectively. Interreader agreement testing between the NEFSC and DFO labs and intra-reader testing at both labs was undertaken. Overall, high agreement was attained, indicating that age determinations at both labs continue to be reliable. Details can be found in Sutherland et al 2007. Age reader agreement was judged to be satisfactory for estimating catch at age.

The 2006 Canadian and USA landings and discards at age estimates by quarter (Table 9 and Figure 8) were summed to obtain the quarterly and annual catch at age and appended to the 1969-2005 catch at age data (Van Eeckhaute and Brodziak 2006). Combined Canada/USA annual catch at age and average Canadian fishery weights and lengths at age are summarized in Tables 10, 11 and 12 and Figures 9 and 10. Canadian and USA fishery weights and lengths at age for 2006 are presented in Table 13. The 2000 year class (age 6), which contributed $56 \%$ of the total catch by numbers, again dominated the fishery in 2006 (Figure 11). Age 6 haddock, the dominant age group for both countries, account for $77 \%$ of USA landings compared to 57\% of the Canadian landings (Figure 8). USA discards represented 48\% by numbers of the USA catch, but only $2 \%$ by numbers of the combined Can/USA catch. Seventynine percent of the USA discards were age 3 haddock.
In 2005, the exceptional 2003 year class had been expected to make up $66 \%$ in numbers of the total EGB catch based on the projection, but the catch of that year class was only $28 \%$ of the observed catch (Figure 11). The shortfall was due to lower than anticipated recruitment of that age group to the fishery. As a result, the 2000 year class and older year classes made up a much higher percentage of the catch than anticipated, $67 \%$ instead of $30 \%$.
The dominant age group in the fishery has increased from ages 2 and 3 during earlier periods to age 4 in recent years due primarily to a change in mesh type and an increase in mesh size. The age composition during the 1969 to 1974 period was atypical since it was dominated by the outstanding 1962 and 1963 year classes which continued to contribute substantially at ages 6 and older (Figure 12).

## Abundance Indices

## Research Surveys

Surveys of Georges Bank have been conducted by DFO each year (February/March) since 1986 and by NMFS each fall (October/November) since 1963 and each spring (April) since 1968. All surveys use a stratified random design (Figures 13 and 14). For the NMFS surveys, two vessels have been employed and there was a change in the trawl door in 1985. Vessel and door type conversion factors (Table 14), derived experimentally from comparative fishing, have been applied to the survey results to
make the series consistent (Forrester et al 1997). Additionally, two different trawl nets have been used on the NMFS spring survey, a modified Yankee 41 during 1973-81 and a Yankee 36 in other years, but no conversion factors are available for haddock.
In 2006, it was necessary to use six sets that were conducted by the Teleost (the Alfred Needler is the vessel usually used for this survey) in stratum $5 Z 3$ to obtain proper coverage for the DFO survey. Although preliminary examination of comparative fishing experiments between the Teleost and Needler indicated that a conversion factor might be warranted, and was used in the previous assessment for these six tows, it was considered preferable to use unconverted data for the current assessment until more thorough analyses and review are conducted. The impact of applying a conversion factor of 1.17 to these 6 tows in the previous assessment, to make them equivalent to Needler tows, resulted in a very small change (1\%) to the 2006 survey index.
The 2006 NMFS fall survey did not have any sets completed in stratum 20. A catch value of zero was assigned to this stratum as very few or no haddock have been caught in this stratum in recent years.
The spatial distribution of catches by age group (1, 2, and 3+ for spring and 0,1 and 2+ for fall) in the most recent surveys is plotted to show the distribution in comparison to the average over the previous 10 year period (Figures 15, 16 and 17). Ages $2+$ in the NMFS 2006 fall survey were abundantly distributed in 5Zj with some good catches on the southern flank as well. The DFO 2007 February survey found adult fish (ages 3+) abundantly and widely distributed on the Canadian side of the bank but catches on the USA side were much more scattered and scarce. However, a month later, during the NMFS spring survey, adult fish were found in large quantities on the US side as well as the Canadian side. Catches of the 2006 year class were sporadic for all three surveys but a few good tows were seen by the DFO survey on the southern flank. Good catches of the 2005 year class were made during all three surveys. In the fall, this year class was widely distributed on the Canadian side. In Feb, the DFO survey found them in highest concentrations on the southern flank and the NMFS spring survey also made good catches there as well as along the northern edge. The spring distribution of age 2 haddock was somewhat atypical as this age group is usually found most abundantly on the northern edge at this time of year.

Age-specific, swept area abundance indices show that the three surveys are consistent and track year class strengths well (Tables 15, 16 and 17; Figure 18). Some year effects are evident. For example, low spring catches occurred in both the 1997 DFO and NMFS surveys. Survey biomass indices (ages 2-8 in fall; 3-8 in spring) peaked during the early 1960s (Figure 19). After declining to a record low in the early 1970s, they peaked again in the late 1970s, though at a lower level, and again during the mid to late 1980s at about half the level of the 1970s peak. Biomass generally increased during the 1990s. Since about 2003, the biomass indices have seen significant fluctuation with a large increase in 2007 for the NMFS spring survey, a small increase in the NMFS fall survey and a decrease in the DFO survey.

All three survey series indicate that the 2003 year class is one of the strongest on record with the age 4 indices for the spring surveys and the age 3 index for the fall survey the highest for those series for those ages. The 3 new survey observations for
the 2005 year class include 2 observations that are intermediate between the previous year's values and one that is near the previous year's lowest value supporting the view that it is an above average year class (Figure 20).

## Growth

Canadian fishery weights at age (Table 11, Figure 10) in 2006 declined for ages 2 to 7, but, 2007 DFO survey weights at age (Table 18 and Figure 10) and lengths at age (Table 19 and Figure 21) generally increased, interrupting a downward trend that started after the mid-1990s for the older ages and around 2001 for the younger ages. The 2007 DFO survey length and weight at age 9+ are low due to being dominated by ages 9 and 10 which have low values for both characteristics. Average size at age has declined substantially so that haddock of age 2 and older are now at or smaller than the size that the next younger age group was in previous years before the declines occurred.

Weights at age from the DFO survey are considered beginning of year population weights and are calculated using the method in Gavaris and Van Eeckhaute (1998) in which weights observed during the survey are weighted by population numbers at length and age. Fishery weights at age are derived from the sampled lengths at age and a length-weight relationship (Waiwood and Neilson 1985).

## Harvest Strategy

The Transboundary Management Guidance Committee (TMGC 2003) has adopted a strategy to maintain a low to neutral risk of exceeding the fishing mortality limit reference, $F_{\text {ref }}=0.26$. When stock conditions are poor, fishing mortality rates should be further reduced to promote rebuilding.

## Estimation of Stock Parameters

## Calibration of Virtual Population Analysis (VPA)

Tuned virtual population analysis was used to estimate stock parameters. The adaptive framework, ADAPT, (Gavaris 1988) was used to calibrate the virtual population analysis with the research survey data. Details of the model formulations and model assumptions can be found in Gavaris and Van Eeckhaute (1998).

The VPA was based on quarterly catch at age, $C_{a, t}$ for ages a $=0,1,2 \ldots 8,9+$, and time $t=1969.0,1969.25,1969.5,1969.75,1970.0 \ldots 2006.75$ where $t$ represents the beginning of the time interval during which the catch was taken. Catch at age 0 (i.e., discards) was included in the catch at age. The population was calculated to the beginning of 2007. The VPA was calibrated to bottom trawl survey abundance indices, $I_{\mathrm{s}, \mathrm{a}, \mathrm{t}}$ for
$s=$ DFO, ages $a=1,2,3 \ldots 8$, time $t=1986.16,1987.16 \ldots 2006.16,2007.00$
$s=$ NMFS spring (Yankee 36), ages $a=1,2,3 \ldots 8$, time $t=1969.29,1970.29$, 1971.29, 1972.29, 1982.29, 1983.29...2006.29, 2007.00
$s=$ NMFS spring (Yankee 41), ages $a=1,2,3 \ldots 8$, time $t=1973.29,1974.29 \ldots 1981.29$
$s=$ NMFS fall, ages $a=0,1,2 \ldots 5$, time $t=1969.69,1970.69 \ldots 2006.69$
Since the population is calculated to beginning year 2007, the NMFS and DFO spring surveys in 2007 were designated as occurring at time 2007.00 Other details of the tuning setup were the same as those used in the previous assessment and can be found in Van Eeckhaute and Brodziak 2006.

Statistical properties of estimators were determined using conditional non-parametric bootstrapping of model residuals (Efron and Tibshirani 1993, Gavaris and Van Eeckhaute 1998). Population abundance estimates at age 1 exhibited a large relative error of $61 \%$ and a large relative bias of $16 \%$, while the relative error for other ages was between $26 \%$ and $41 \%$ with a relative bias between $3 \%$ and $6 \%$ (Table 20). The relative bias on fishing mortality for ages 4 and older in 2006 was small at about $2 \%$. While trends in the three surveys are generally consistent, the survey indices exhibit high variability and the average magnitude of residuals is large relative to other assessments. Although several large residuals were apparent, these do not appear to have a substantial impact on estimates of current abundance (Figures 22-26). Some patterns in the residuals (by cohort and by age) suggest year class and/or year effects.

## Retrospective Analysis

Retrospective analyses were used to detect any patterns to consistently overestimate or underestimate fishing mortality, biomass and recruitment relative to the terminal year estimates. This stock assessment does not display a retrospective pattern. While recruitment estimates may sometimes change substantially when more data becomes available, e.g., the 1998, 2000 and 2003 year classes, successive estimates of year class abundance at age do not display any persistent tendency to be higher or lower (Figure 27). Similarly, retrospective analysis showed no persistent patterns in the estimates of adult biomass (ages 3-8) or fishing mortality (ages 4-8 weighted by population numbers) (Figure 28).

## State of Resource

The state of the resource was based on results from an age structured analytical assessment (VPA) that used fishery catch statistics and sampling for size and age composition of the catch (landings plus discards) for 1969 to 2006. The VPA was calibrated to trends in abundance from three bottom trawl survey series; NMFS spring, NMFS fall and DFO. For each cohort, the terminal population abundance estimates from ADAPT were adjusted for bias estimated from the bootstrap, and used to construct the history of stock status (Tables 21, 22 and 23). This approach for bias adjustment was considered preferable to using potentially biased point estimates of stock parameters (O'Boyle 1998). The weights at age from the DFO survey (Table 18) were used to calculate beginning of year population biomass (Table 23). A weight of 2.4 kg , which was midway between the age 6 and 8 weight for that cohort, was used for age 7 in 1995 as no data were available for that age group. The 1986-95 average weight at each age was used for 1969-85. Data to approximate the age composition of the catch
from unit areas 5Zj and 5Zm during 1931 to 1955 were used to reconstruct a population analysis of EGB that was suitable for comparison of productivity.
The adult (ages 3+) biomass trend compared favorably with the survey adult biomass trends (scaled with catchabilities) (Figure 29). Population biomass (ages 3+) increased to $39,000 \mathrm{mt}$ during the late 1970 s and early 1980 s due to recruitment of the strong 1975 and 1978 year classes whose abundances were estimated to be above 50 million age-1 fish each (Figure 30). However, biomass declined rapidly in the early 1980s as subsequent recruitment was poor and these two cohorts were fished intensely at young ages. Improved recruitment in the 1990s and the strong 2000 year class, lower exploitation, and reduced capture of small fish in the fisheries allowed the biomass to increase from near an historical low of $8,500 \mathrm{mt}$ in 1993 to $69,500 \mathrm{mt}$ in 2003. Adult biomass subsequently decreased to 46,900 mt in 2005 but increased in 2006 and 2007 and is now at 145,300 mt (80\% Confidence Interval: 113,276-200,206 mt), higher than the 1931-1955 maximum biomass of about $90,000 \mathrm{mt}$. The marked increase is due to the exceptional 2003 year class, estimated at $122,900 \mathrm{mt}$ at age 4 . Older ages sustained the fishery in 2006 but the exceptional 2003 year class is expected to contribute substantially to the catch weight in 2007.
Recruitment improved in the 1990s and the exceptional 2003 year class, estimated at 321 million age-1 fish, is the largest in the assessment time series (1931-1955 and 1969-2005). The 2000 year class ( 69 million at age 1) is estimated to be larger than the strong 1975 and 1978 year classes (Figure 30). In contrast, the 2001, 2002 and 2004 year classes, at less than 8 million fish, are below the 18 million average of the 10 most recent year classes (excluding the 2003 year class), while the 2005 year class at 31 million is above the 10-year average. Initial estimates of the 2006 year class suggest that it is about the size of the 2004 year class.
Fishing mortality for ages 4+ (weighted by population abundance) fluctuated between 0.2 and 0.4 during the 1980s (Figure 31) and markedly increased between 1989 and 1993 to about 0.6, the highest observed. Since 1995, fishing mortality had been below the reference, $F_{\text {ref }}=0.26$, but increased in 2005 and 2006 to above $F_{\text {ref }}\left(F_{2006}=0.36\right.$; 80\% Confidence Interval: 0.28-0.49).

The partial recruitment at age for EGB haddock has decreased in recent years (Tables 24 and 25; Figure 32) and, consequently, fishing mortality based on ages 5+, as fully recruited, has been higher than $F$ for ages 4+ since 2003 (Figure 31). Lower weights at age have resulted in a reduced partial recruitment so that age 4 is now no longer fully recruited to the fishery. Therefore, partial recruitment estimates for ages 1 to 4 for recent years are more appropriately normalized on ages 5-8 (Table 26). Due to the magnitude of the 2003 year class, the partial recruitment pattern used for this year class will have a significant impact on estimates of the magnitude and composition of future catches.

Gains in fishable biomass may be partitioned into those associated with somatic growth of haddock, which have previously recruited to the fishery, and those associated with new recruitment to the fishery (Rivard 1980). We used age 2 as the age of first recruitment to the fishery. This choice facilitated comparisons with historic stock productivity but may be less representative of the current fishery selectivity. Since 1993,
except for 1996, 2001, 2003 and 2004, surplus production (biomass gains from growth and from recruitment, decremented by losses due to natural deaths) has exceeded fishery harvest yields, resulting in net population biomass increases (Figure 33). Growth of fish is the dominant component of the biomass gain but recruitment accounts for significant portions when stronger year classes enter the population, e.g. the 2000 year class in 2002 and the 2003 year class in 2005 (Figure 34). The biomass contributed by the 2003 year class, both when it recruited at age 2 and through growth during that year was greater than that of any other previous cohort since 1969.

## Productivity

Stock characteristics such as recruits per spawner, age structure, spatial distribution and fish growth reflect changes in the productive potential.
Stock-recruitment data indicates that the chance of a good year class is significantly enhanced for adult biomass above about $40,000 \mathrm{mt}$ (Figure 35). Since 1969, only the 1975, 1978, 2000 and 2003 year classes have been above the average abundance of year classes observed during the period 1931-55. The recruits per adult biomass ratio was generally low during the 1980s but higher during the 1990s, comparable to that in the 1931-1955 period (Figure 36), when the 3+ biomass was above $40,000 \mathrm{mt}$. Since 2001, with the exception 2003 and 2005, recruits per spawner have again been low.
In both absolute numbers and percent composition, the population age structure displays a broad representation of age groups (Figure 35), reflecting improving recruitment and lower exploitation, particularly at younger ages, since 1995.
The spatial distribution patterns observed during the most recent bottom trawl surveys were similar to the average patterns over the previous ten years. However, consistent with the pattern observed for previous large year classes, the exceptional 2003 year class, the main component of the 3+ age group, was widely distributed throughout the survey area (Figures 15, 16 and 17).
Both length and weight at age have declined since about 2000. While size at age increased in 2007 for most ages, weights remained about $40 \%$ to $50 \%$ below the average during 1986 to 2000. The size at age for the 2003 year class is smaller than previous year classes. DFO survey average weights at length, used to reflect fish condition, exhibit a declining trend but improved in 2007 (Figure 38).
In summary, with expanded age structure, broad spatial distribution and generally higher recruit per spawner ratio, resource productivity is high, negatively impacted only by recent reductions in fish size at age.

## Outlook

This outlook is provided in terms of consequences with respect to the harvest reference points for alternative catch quotas in 2008. Uncertainty about standing stock generates uncertainty in forecast results which is expressed here as the risk of exceeding $\mathrm{F}_{\text {ref }}=0.26$. The risk calculations assist in evaluating the consequences of alternative catch quotas by providing a general measure of the uncertainties. However, they are
dependent on the data and model assumptions and do not include uncertainty due to variations in weight at age, partial recruitment to the fishery, natural mortality, systematic errors in data reporting or the possibility that the model may not reflect stock dynamics closely enough.
As in the previous assessment for this stock, the 2003 year class will comprise a large portion of the catch for the projected year, 2008. Predictions of weights at age and partial recruitment for this year class used for input into the risk assessment are very influential for catch projections.
For projections, the weights at age for the 2003 year class were derived by accounting for recent trends in reduced growth rate, as demonstrated by the 1998, 1999 and 2000 year classes (Figure 39), as was done for the previous assessment (Van Eeckhaute and Brodziak 2006). Data points at younger ages were excluded as the addition of these points changed the functional relationship from linear to curvilinear. The predicted growth rate at length was applied to the 2007 DFO survey average length for the 2003 year class ( 41 cm at age 4) to obtain the beginning of year length at age 5, i.e. L4=L3 $x$ $e^{\text {growth rate }}$, and then sequentially, at age 6 using the growth rate predicted for the length at age 5 (Table 26). Average fishery lengths were determined from the relationship between beginning year length (from the DFO survey) and the fishery length in the same year using data from 1995 to 2006 (Figure 40). The resulting 2003 year class predicted lengths used for the population and fishery are compared to other year classes in Figure 41. The length estimates were then converted to weights using the length weight relationship used to convert the Canadian fishery lengths to weights (Waiwood and Neilson 1985). Beginning of year weights at age were reduced by $10 \%$ to account for the observed reduction in observed weights relative to those derived from the length weight relationship (Table 27). Weights at age for the fishery, derived from the length weight relationship, were considered appropriate as this relationship is based on fishery data (Table 28). The 2006 observed fishery weights were used for year classes preceding and following the 2003 year class.
The Canadian groundfish fishery switched from diamond mesh to square mesh around 1995. The relationship between partial recruitment values from 1995 to 2006 and fishery weights, which reflect fishery lengths, was used to determine partial recruitment values (Figure 42). A drop in age 4 partial recruitment compared to age 5 is observed after 2002 (Table 24). Therefore, for Figure 42, the 1995 to 2002 partial recruitment values were based on ages 4-8 as fully recruited while the 2003 to 2006 values were based on ages 5-8. Values of 0.2 for age 4 in 2007 and 0.52 for age 5 in 2008 were judged to be appropriate for the 2003 year class for the catch projection.
A risk assessment was conducted to beginning year 2009 incorporating these patterns in growth and partial recruitment. Stock size estimates at the beginning of 2007 were used to start the forecasts. Abundances of the 2007 and 2008 year classes were assumed to be 20 million at age 1, which is near the previous 10-year average (2003 year class excluded). Natural mortality was assumed to be 0.2 (Table 29). Assuming a 2007 catch equal to the $19,000 \mathrm{mt}$ total quota, a combined Canada/USA catch of $26,700 \mathrm{mt}$ in 2008 would result in a neutral risk (50\%) that the fishing mortality rate in 2008 will exceed $F_{\text {ref }}=0.26$ (Figure 42). A catch of $23,000 \mathrm{mt}$ would result in a low risk (25\%) that the fishing mortality rate in 2008 will exceed $F_{\text {ref }}$. Adult biomass is projected
to be $151,000 \mathrm{mt}$ at the beginning of 2009 a drop of $7 \%$ from the previous year (Table 30). The 2003 year class (age 5) will comprise the highest proportion of the total 2008 yield accounting for $86 \%$ of the catch in weight, $88 \%$ by numbers, at the $26,700 \mathrm{mt}$ level. Ages $6+$ are expected to account for $12 \%$ of the catch biomass, $9 \%$ by numbers.

## Special Considerations

The outstanding 2003 year class was expected to contribute $66 \%$ of the 2006 catch numbers but accounted for only $28 \%$. The contribution was less than predicted due to lower than anticipated recruitment to the fishery. The failure of this year class to contribute as expected to the fishery resulted in more of the 2000 and older year classes being caught in 2006 than had been projected from the 2005 assessment. This generated a fishing mortality above $\mathrm{F}_{\text {ref }}$ on the older ages in 2006. Slow growth of the 2003 cohort will continue to impact the fishery. If the TAC in 2007 is caught, fishing mortality will, again, be higher than $F_{\text {ref }}$ on the fully recruited ages ( $F_{5+}=0.33$ ) because the 2007 age 4 fishery partial recruitment is now estimated at 0.2 compared to 0.3 , the value used in the 2006 assessment.

While best judgment was used to determine the fishery partial recruitments for the reduced weight of the 2003 year class, the risk analysis does not capture the extent of uncertainty of the consequences for various catch levels. To characterize the dependence of the projection results on the fishery partial recruitment for the 2003 year class, a sensitivity analysis was done to augment the risk analysis. Using the observed range of partial recruitment at fishery weight during 1995 to 2006, the 2008 projected catch could vary from $17,000 \mathrm{mt}$ to $31,000 \mathrm{mt}$. If the realized partial recruitment is near the higher end of the observed partial recruitment range, the fishery could forego available yield, if it is lower, the 4+ fishing mortality could be higher than $\mathrm{F}_{\text {ref. }}$

Cod and haddock are often caught together in groundfish fisheries, although their catchabilities to the fisheries differ and they are not necessarily caught in proportion to their relative abundance. With current fishing practices and catch ratios, the achievement of rebuilding objectives for cod may constrain the harvesting of haddock. Modifications to fishing gear and practices, with enhanced monitoring, may mitigate these concerns.

## Acknowledgements

G. Donaldson, E. Williams, and P. Comeau of DFO and Javitech Ltd. provided samples from the Canadian fishery. We thank members of the fishing industry who spent time to discuss their experiences in the fishery. We also thank Donald Clark and Fred Serchuck for reviewing the draft manuscript.

Table 2. Regulatory measures implemented for the $5 Z$ and EGB fishery management units by the USA and Canada, respectively, from 1977, when jurisdiction was extended to 200 miles for coastal states, to the present.

|  | USA | Canada |
| :---: | :---: | :---: |
| 1977-82 | Mesh size of $51 / 8^{\prime \prime}$ ( 140 mm ), seasonal spawning closures, quotas and trip limits. |  |
| 1982-85 | All catch controls eliminated, retained closed area and mesh size regulations, implemented minimum landings size ( 43 cm ). | First 5Ze assessment in 1983. |
| $\begin{aligned} & 1984 \\ & \text { Oct. } \end{aligned}$ | Implementation of the 'Hague' line . |  |
| 1985 | $51 / 2^{\prime \prime}$ mesh size, Areas 1 and 2 closed February-May. |  |
| 1989 |  | Combined cod-haddock-pollock quota for 4X5Zc |
| 1990 |  | EGB adopted as management unit. For MG < 65 ft . - trip limits with a $30 \%$ bycatch of haddock to a maximum of 8 trips of 35,000 lbs per trip between June 1 and Oct. 31 and 130 mm square mesh required. Fixed gear required to use large hooks until June |
| 1991 | Established overfishing definitions for haddock. | MG < 65 ft similar to 1990 but mesh size increased to 145 mm diamond. |
| 1992 |  | Introduction of ITQs and dockside monitoring. Total allowable catch $(T A C)=$ 5000 mt . |
| 1993 | Area 2 closure in effect from Jan 1-June30. | OT fishery permitted to operate in Jan. and Feb. Increase in use of square mesh. TAC $=5000$ mt. |
| 1994 | Jan.: Expanded Area 2 closure to include June and increased extent of area. <br> Area 1 closure not in effect. <br> 500 lb trip limit. <br> Catch data obtained from mandatory log books combined with dealer reports (replaces interview system). <br> May: 6" mesh restriction. <br> Dec.: Area 1,2 closed year-round. | Spawning closure extended to Jan. 1 to May 31. <br> Fixed gear vessels must choose between $5 Z$ or $4 X$ for the period of June to September. <br> Small fish protocol. <br> Increased at sea monitoring. <br> OT > 65 could not begin fishng until July 1. <br> Predominantly square mesh by end of year. <br> $\mathrm{TAC}=3000 \mathrm{mt}$. |
| 1995 |  | All OT vessels using square mesh. Fixed gear vessels with a history since 1990 of 25 t or more for 3 years of cod, haddock, pollock, hake or cusk combined can participate in $5 Z$ fishery. <br> ITQ vessel require at least 2 t of cod and 8 t of haddock quota to fish Georges. TAC $=2500$ mt . <br> Restrictions on catching of cod and haddock under 43 cm (small fish protocol). |
| 1996 | July: Additional Days-at-Sea restrictions, trip limit raised to 1000 lbs. | Fixed gear history requirement dropped. TAC $=4500 \mathrm{mt}$. |
| 1997 | May: Additional scheduled Days-at-sea restrictions. | Vessels over 65 ft operated on enterprise allocations, otter trawlers under 65 ft on |

|  | USA | Canada |
| :---: | :---: | :---: |
|  | September: Trip limit raised to $1000 \mathrm{lbs} /$ day, maximum of $10,000 \mathrm{lbs} /$ trip. | individual quotas, fixed gear vessels $45-65 \mathrm{ft}$ on self-administered individual quotas and fixed gear vessels under 45 ft on community quotas administered by local boards. TAC = 3,200 mt. |
| 1998 | Sept. 1: Trip limit raised to $3000 \mathrm{lbs} /$ day, maximum of $30,000 \mathrm{lbs} /$ trip. | Fixed gear vessels $45-65 \mathrm{ft}$ operated on individual quotas. TAC $=3,900 \mathrm{mt}$. |
| 1999 | May 1: Trip limit 2,000 Ibs/day, max. 20,000 lbs/trip. <br> Square mesh size increased to 6.5" (diamond is 6 "). <br> June 15: Scallop exemption fishery in Closed Area II. <br> Nov. 5: Trip limit 5,000 lbs/day, max. 50,000 lbs/trip. | TAC $=3,900 \mathrm{mt} . ;$ mandatory cod separator panel when no observer on board. |
| 2000 | October: Daily trip limit suspended to April 2001but retained max. trip limit of 50,000 lbs/trip. | TAC $=5,400 \mathrm{mt}$. |
| $\begin{aligned} & \hline 2001- \\ & 2002 \\ & \hline \end{aligned}$ | Day and trip limit adjustments. Daily trip limit suspended July 5, 2002. | TAC $=6,989$ and 6,740 mt for 2001 and 2002 respectively. |
| $\begin{aligned} & 2002- \\ & 2003 \\ & \hline \end{aligned}$ | 30,000-50,000 lb/trip limit. <br> Trip limit suspended in Oct. 2003. | TAC $=6,933 \mathrm{mt} \mathrm{for} 2003$. |
| Canada - USA Resource Sharing Agreement on Georges Bank |  |  |
| 2004 | May 1, day and trip limits removed. TAC = $5,100 \mathrm{mt}$. Oct. 1: unit areas 561 and 562 closed to groundfish vessels. Nov. 19: Special Access Program (SAP) for haddock opened. Dec. 31: Haddock SAP closed. | TAC $=9,900 \mathrm{mt}$. |
| 2005 | TAC= 7,590 mt. Jan. 14: cod separator trawl required. | TAC $=15,410 \mathrm{mt}$; exploratory winter fishery Jan. to Feb. 18, 2005. |
| 2006 | TAC $=7,480 \mathrm{mt}$; Closed in first half of year when cod quota nearly reached. | TAC $=14,520 \mathrm{mt}$; exploratory winter fishery Jan. to Feb. 6, 2006. |

OTB=Otter Trawl Bottom, LL=Long Line, GN=Gill Net, HL=Hand Line, DR=Scallop Dredge
${ }^{1}$ Discards from the scallop fishery were estimated by quarter.
${ }^{2}$ Ages for 2 length groupings were estimated and are not included in the total.
${ }^{3}$ Ages for 5 length groupings were estimated and are not included in the total.
${ }^{4}$ Ages for 5 length groupings were estimated and are not included in the total.
${ }^{5}$ Ages for 7 length groupings were estimated and are not included in the total.
${ }^{6}$ Combined with August LL.
${ }^{7}$ Combined with October LL.
${ }^{8}$ Otoliths were not available for some lengths. Ages at these lengths with no otoliths sampled were estimated by comparing to other quarters and year class strengths.

Table 8. USA landings of haddock in 2006 by quarter and market category from EGB and NMFS sampling intensity for lengths and ages.

| Market Category | Large | Scrod | Unclassified | Total |

Table 16. Total swept area estimated abundance at age (numbers in 000's) of EGB haddock from NMFS spring surveys during 1968-2007. From 1973-81, a 41 Yankee trawl was used while a 36 Yankee trawl was used in other years. Conversion factors to adjust for changes in door type and survey vessel were applied.

Figure 1. Fisheries statistical unit areas in NAFO Subdivision 5Ze. Alpha-numeric codes, e.g. 5Zej, are DFO designations and numeric codes, e.g. 561, are NMFS designations.

Figure 2. Historical catch of EGB haddock during 1931-1955 compared to recent catches during 19692006.

Figure 3. Nominal catch of EGB haddock during 1969-2006.

Figure 4. Haddock catches in EGB by month and gear for the Canadian commercial groundfish fishery in 2006 (wide bars) with sampling levels (narrow bars).

Figure 5. Catch at length by the principal Canadian EGB commercial haddock fisheries in 2006. In the lower graph the scallop dredge length frequency is expanded according to the axis on the right.

Figure 6. Catch at length by quarter for the Canadian EGB commercial haddock fisheries in 2006.

Figure 7. Catch at length of haddock by the USA EGB groundfish fisheries in 2006.

Figure 8. Composition in numbers and percent of the EGB haddock Canadian and USA landings and discards in 2006.

Figure 9. Total commercial catch at age (numbers) of EGB haddock during 1969-2006. The bubble area is proportional to magnitude.

Figure 10. Average weights at age for EGB haddock from the Canadian commercial groundfish fishery during 1969-2006 and from the DFO survey during 1986-2007.

Figure 11. Actual and projected 2006 EGB haddock catch in percent composition

Figure 12. Age composition of the haddock catch for the EGB commercial fishery during 1969-1974, 1975-1984, 1985-1994, and 1995-2004.

Figure 13. Stratification scheme used for NMFS surveys. The EGB management area is indicated by shading.

Figure 14. Stratification scheme used for the DFO survey. The EGB management area is indicated by shading.

Figure 15. Distribution of EGB haddock abundance (number/tow) as observed from the NMFS fall survey. The squares (left panels) are shaded relative to the average catch for 1995 to 2005. The expanding symbols (right panels) represent the 2006 survey catches.

Figure 16. Distribution of EGB haddock abundance (number/tow) as observed from the DFO survey. The squares (left panels) are shaded relative to the average catch for 1996 to 2006. The expanding symbols (right panels) represent the 2007 survey catches.

Figure 17. Distribution of EGB haddock abundance (number/tow) as observed from the NMFS spring survey. The squares (left panels) are shaded relative to the average catch for 1996 to 2006. The expanding symbols (right panels) represent the 2007 survey catches.

Figure 18. Estimated abundance at age (numbers in 000's) of EGB haddock for the DFO, NMFS spring and NMFS fall surveys during $1963-2007$. Bubble area is proportional to magnitude (see Tables 14-16). Conversion factors to adjust for changes in door type and survey vessel were applied to the NMFS surveys. From 1973-81 (pale circles), a 41 Yankee trawl was used for the NMFS spring survey while a 36 Yankee was used in the other years. Symbol size has not been adjusted between surveys for the catchability of the survey.

Figure 19. Biomass from NMFS fall (ages 2-8), NMFS spring (ages 3-8) and DFO (ages 3-8) research surveys (scaled by calibration constants) for EGB haddock during 1963-2007.

Figure 20. Year-class abundance for ages 0 and 1 from the NMFS fall survey and ages 1 and 2 from the NMFS spring and DFO research surveys (scaled by calibration constants) for EGB haddock during 19632007.

Figure 21. Length at age for EGB haddock derived from DFO surveys during 1986-2007.

Figure 22. Residuals by year and age group for research survey indices during 1969-2006 for EGB haddock. Solid symbols indicate positive values, open symbols indicate negative values. Bubble area is proportional to magnitude. From 1973-81 (pale circles), a 41 Yankee trawl was used for the NMFS spring survey while a 36 Yankee was used in the other years.

Figure 23. Age by age plots of the observed and predicted In abundance index versus In population numbers for EGB haddock from the DFO survey during 1986-2007.

Figure 24. Age by age plots of the observed and predicted In abundance index versus In population numbers for EGB haddock from the NMFS spring survey with a Yankee 36 net during 1969-1972 and 1982-2007.

Figure 25. Age by age plots of the observed and predicted In abundance index versus in population numbers for EGB haddock from the NMFS spring survey with a Yankee 41 net during 1973-1981.

Figure 26. Age by age plots of the observed and predicted In abundance index versus In population numbers for EGB haddock from the NMFS fall survey 1969-2006.

Figure 27. Retrospective estimates of EGB haddock year-class abundance as additional years of data were included in the assessment did not display any persistent trends.

Figure 28. Retrospective estimates from VPA of EGB haddock biomass and fishing mortality did not display any persistent trends for over or under estimation as successive years of data were excluded in the assessment.

Figure 29. The EGB adult haddock (ages 3+) biomass trend from VPA compared with the survey adult biomass (scaled with catchabilities) trends.

Figure 30. Beginning of year adult (3+) biomass and number of age 1 recruits for EGB haddock during 1931-1955 and 1969-2007.

Figure 31. Fishing mortality rate (weighted by population) for EGB haddock ages 4+ and 5+ during 19692006 and the fishing mortality threshold reference established at $\mathrm{F}_{\text {ref }}=0.26$.

Figure 32. Average partial recruitment of EGB haddock for 3 time periods compared to the years 2005 and 2006. The partial recruitment is normalized to either ages $4-8$ or $5-8$, as indicated.

Figure 33. Surplus production of EGB haddock available to the commercial fishery compared to the harvested yield during 1969-2006.

Figure 34. Amount of productivity attributible to growth (ages 2 to $9+$ ) of EGB haddock and the amount contributed by recruitment (age 2) during 1969-2006.

Figure 35. Relationship between EGB adult (ages 3+) haddock biomass and recruits at age during 19311955 and during 1969-2006.

Figure 36. Ratio of recruits (numbers at age 1) to spawning biomass (kg) for EGB haddock during 19311955 and during 1969-2006.

Figure 37. The age composition and absolute abundance at age of the EGB haddock population in 2007 compared to averages during 1931-1955, 1969-1974, 1975-1984, 1985-1994, and 1995-2005.

Figure 38. DFO survey weights at lengths for EGB haddock for six 2 cm length groupings during 19862007.

Figure 39. Relationship between length and growth rate derived for EGB haddock using observed growth increments from the 1998, 1999 and 2000 year classes.

Figure 40. Relationship between EGB haddock beginning of year lengths (from DFO surveys) for 1995 to 2006 to average fishery lengths for the same year smoothed with a Loess smoothing algorithm (Clevand 1979). The lengths of the 2003 haddock year class at age $4(41 \mathrm{~cm})$ and age $5(46.2 \mathrm{~cm})$ with the corresponding fishery lengths are indicated. The 1:1 line is added for illustrative purposes.

Figure 41. Average population lengths at age and average fishery lengths at age of the 1997 to 2000 and 2003 year classes of EGB haddock as observed from the DFO survey. Predicted lengths for the 2003 year class are indicated by $\rangle$.

Figure 42. Fishery weight and partial recruitment relationship observed for EGB haddock in 2003 to 2005. A smoothed line was fitted to the data using a loess algorithm (Cleveland 1979). The 2003 year class predicted fishery weight at age $4(1.263 \mathrm{~kg})$ and $5(1.507 \mathrm{~kg})$ with the corresponding partial recruitment ( 0.2 and 0.52 , respectively) are indicated by the dotted lines. The gray lines approximate the upper and lower range of partial recruitment values.

Figure 43. Risk of 2008 fishing mortality exceeding $F_{\text {ref }}=0.26$ for EGB haddock for increasing catch quotas.

[^0]:    ${ }^{1}$ Total includes catches for tonnage classes which are not listed, only tonnage classes with substantial catches listed
    ${ }^{2}$ Catches of $26 \mathrm{t}, 776 \mathrm{t}$, 1091t and 2 t for side otter trawlers and stern otter trawlers tonnage classes 2,3 and 5 respectively were excluded because of suspected area misreporting.
    ${ }^{3}$ Tonnage class 1 landings included in 'Total'. Historically, tonnage class 1 accounted for a low proportion of total otter trawl landings but the proportion has increased in recent years..

[^1]:    ${ }^{1}$ One haddock measured
    ${ }^{2}$ Excludes 2005 value.

[^2]:    ${ }^{1}$ Observed 2007 beginning year length or weight for 2003 year class from DFO survey
    ${ }^{2}$ weight $=0.0000158 \times$ length ${ }^{2.91612}$ (Waiwood and Neilson 1985)
    ${ }^{3}$ Weight reduced by $10 \%$ to reflect lower values for survey weights versus fishery weights
    ${ }^{4}$ Calculated length
    ${ }^{5}$ Estimated from relationship between beginning of year (DFO survey) and fishery lengths the same year.

[^3]:    ${ }^{1}$ Estimated from observed 2005 partial recruitment except where indicated.
    ${ }^{2}$ Derived from relationship between 2003 to 2005 survey lengths at age and partial recruitment values.
    ${ }^{3}$ Equal to 2006 DFO survey weights except where indicated.
    ${ }^{4}$ Estimated weights based on a growth model for the 2003 year class and reduced by $10 \%$ to reflect lower condition (see Table 28).
    ${ }^{5}$ Equal to 2006 Canadian fishery weights except where indicated.
    ${ }^{6}$ Estimated weights based on a growth model for the 2003 year class.
