#### Abstract

The total catch of eastern Georges Bank (EGB) haddock in 2007 was $12,680 \mathrm{mt}$ of the 19,000 mt combined Canada/United States of America (USA) quota. The 2007 Canadian catch decreased from 12,051 in 2006 to $11,951 \mathrm{mt}$ while the USA catch increased from 591 mt in 2006 to 729 mt . Canadian scallop fishery discards were estimated at 61 mt and USA groundfish fishery discards were estimated at 482 mt . EGB haddock catches fluctuated around 5,000 mt during 1985-1990. Under restrictive management measures, combined Canada/USA catches declined from over 6,500 mt in 1991 to a low of about 2,200 mt in 1995, averaged about 3,600 mt during 1996-1999 and have increased since then.

Adult population biomass (ages $3+$ ) has steadily increased from near an historical low of $9,000 \mathrm{mt}$ in 1993 to $77,000 \mathrm{mt}$ in 2003. Adult biomass decreased to about $54,000 \mathrm{mt}$ at the beginning of 2005 but subsequently tripled to a record-high $158,100 \mathrm{mt}$ in 2008, higher than the 1931-1955 maximum of about 90,000 mt. The exceptional 2003 year class, estimated at 322.7 million age-1 fish, is the largest observed in the assessment time series (1931-1955 and 19692005). The 2001, 2002, 2004 and 2006 year classes, at less than 8 million, and the initial estimate of the 2007 year class at 14 million are below the recent 10 year average (excluding the 2003 year class) of 18 million fish. The 2005 year class, at 27 million, is above the average. The age at full recruitment to the fishery increased in 2003 from Age 4 to Age 5 due to the decrease in size at age. Fishing mortality (ages 4+ for pre 2003 and Age 5+ for 2003 to present) was below $F_{\text {ref }}=0.26$ during 1995 to 2003. The failure of the 2003 year class to recruit as expected to the 2005 and 2006 fishery resulted in fishing mortality in 2005 and 2006 exceeding $F_{\text {ref }}$ but $F$ declined to 0.14 in 2007. With expanded age structure, broad spatial distribution and improved recruitment, current resource productivity is high, hindered only by recent reductions in fish weight at age. However, growth in length remains similar to previous years.

Assuming a 2008 catch equal to the $23,000 \mathrm{mt}$ total quota, a combined Canada/USA catch of $33,000 \mathrm{mt}$ in 2009 would result in a neutral risk (50\%) that the fishing mortality rate in 2009 will exceed $F_{\text {ref }}=0.26$. A catch of $28,000 \mathrm{mt}$ would result in a low risk ( $25 \%$ ) that the fishing mortality rate in 2009 will exceed $\mathrm{F}_{\text {ref }}$. However, there is high uncertainty in the partial recruitment estimated for the 2003 year class. Using the observed range of partial recruitment at fishery weight during 1995 to 2006, the 2009 projected catch could vary from 29,000 mt to $36,000 \mathrm{mt}$.

## RÉSUMÉ

Les prises totales d'aiglefin dans l'est du banc Georges en 2007 se sont chiffrées à 12680 tm, par rapport à un TAC combiné Canada-États-Unis de 19000 tm . Les prises canadiennes ont diminué, passant de 12051 tm en 2006 à 11951 tm en 2007, tandis que celles des États-Unis ont augmenté, passant de 591 tm en 2006 à 729 tm en 2007. Les rejets en provenance de la pêche du pétoncle au Canada et de la pêche du poisson de fond aux États-Unis ont été estimés à 61 tm et 482 tm respectivement. Les fluctuations des prises d'aiglefin dans l'est du banc Georges ont été d'environ 5000 tm au cours de la période 1985-1990. Des mesures de gestion strictes ont fait baisser les prises combinées du Canada et des États-Unis, qui, après avoir dépassé 6500 tm en 1991, sont tombées à un creux d'environ 2200 tm en 1995. Ces prises se sont ensuite situées en moyenne à 3600 tm de 1996 à 1999 et elles ont augmenté depuis.

La biomasse de la population d'adultes (âges 3+) a constamment augmenté, passant du creux quasi historique de 9000 tm qu'elle avait connu en 1993 à 77000 tm en 2003. Elle est tombée à 54000 tm au début de 2005, mais a triplé par la suite, pour atteindre un pic record de 158100 tm en 2008, soit un niveau plus élevé que le maximum pour 1931-1955 de 90000 tm . L'exceptionnelle classe d'âge 2003, estimée à 322,7 millions de sujets d'âge 1 , est la plus abondante classe d'âge observée dans les séries chronologiques des évaluations (1931-1955 et 1969-2005). En revanche, les classes d'âge 2001, 2002, 2004 et 2006, chiffrées à moins de 8 millions de sujets, et la classe d'âge 2007, estimée à 14 millions de sujets, se situent sous la moyenne des 10 dernières années, soit 18 millions. La classe d'âge 2005, avec un effectif de 27 millions, est supérieure à la moyenne. L'âge au plein recrutement à la pêche a augmenté en 2003, de l'âge 4 à l'âge 5, en raison de la diminution de la taille selon l'âge. La mortalité par pêche (parmi les âges 4+ avant 2003 et parmi les âges 5+ de 2003 à ce jour) a été inférieure à $F_{\text {rét }}=0,26$ de 1995 à 2003. Le recrutement attendu de la classe d'âge 2003 à la pêche de 2005 et de 2006 ne s'étant pas produit, la mortalité par pêche de 2005 et de 2006 a été supérieure à Fréf, mais $F$ a diminué en 2007, à 0,14. En raison de l'élargissement de la structure des âges, de la vaste distribution spatiale et du taux de recrutement plus élevé, la productivité de la ressource est élevée à l'heure actuelle, n'ayant subi comme effet négatif que les réductions récentes du poids selon l'âge. Le taux de croissance selon la longueur demeure toutefois semblable à ce qu'il était les années précédentes.

Si les prises en 2008 étaient égales au TAC de 23000 tm , des prises combinées Canada/ÉtatsUnis de 33000 tm en 2009 se traduiraient par un risque neutre ( $50 \%$ ) que la mortalité par pêche dépasse $F_{\text {rét }}=0,26$ en 2009. Des prises de 28000 tm aboutiraient à un faible risque ( $25 \%$ ) que la mortalité par pêche dépasse $F_{\text {réf }}$ en 2009. D'après la fourchette des valeurs observées dans le recrutement partiel selon le poids de 1995 à 2006, les prises projetées pour 2009 pourraient varier entre 29000 tm et 36000 tm .

## INTRODUCTION

For the purpose of developing a sharing proposal and consistent management by Canada and the United States of America (USA), an agreement was reached that the transboundary management unit for haddock would be limited to the eastern portion of Georges Bank (EGB) (DFO statistical unit areas $j$ and $m$ in NAFO sub-division 5Ze; USA statistical areas 551, 552, 561 and 562 in NAFO sub-division 5Ze; Figure 1; DFO 2002). This assessment applies the approach used by Van Eeckhaute et al. (2007) to Canadian and USA fisheries information updated to 2007. Results from the Fisheries and Oceans Canada (DFO) survey, updated to 2008, and the USA National Marine Fisheries Service (NMFS) surveys in the spring, updated to 2008, and fall, updated to 2007, were incorporated.

## FISHERY

## Commercial Catches

## Canadian

Haddock on Georges Bank have supported a commercial fishery since the early 1920s (Clark et al.1982). Catches from EGB during the 1930s to 1950s ranged between $15,000 \mathrm{mt}$ and $40,000 \mathrm{mt}$ (Figure 2), averaging about $25,000 \mathrm{mt}$ (Schuck 1951, R. Brown pers. com.). Records of catches by unit area for the early 1960s period have not been located, however, based on records for NAFO Subdivision 5Ze, catches from EGB probably attained record high levels of about $60,000 \mathrm{mt}$ during the early 1960s. Catches in the late 1970s and early 1980s (Table 1), ranging up to about $23,000 \mathrm{mt}$, were associated with good recruitment. Substantial quantities of small fish were discarded in those years (Overholtz et al. 1983). Catches subsequently declined and fluctuated around $5,000 \mathrm{mt}$ during the mid to late 1980s. Under restrictive management measures (Table 2), combined Canada/USA catches declined from over 6,500 mt in 1991 to a low of about $2,100 \mathrm{mt}$ in 1995, fluctuated between about $3,000 \mathrm{mt}$ and $4,000 \mathrm{mt}$ until 1999 and increased to $15,112 \mathrm{mt}$ in 2005 (Figure 3). In 2007, the Canadian catch was $11,951 \mathrm{mt}$ and the USA catch was 729 mt with quotas of $12,730 \mathrm{mt}$ for Canada and $6,270 \mathrm{mt}$ for the USA for a total combined catch of 12,680 mt (combined quota was 19,000 mt).

Some elements of the management measures used on EGB are described in Table 2. Quotas are the principal means used to regulate the Canadian groundfish fisheries on Georges Bank. Quota regulation requires effective monitoring of fishery catch. Weights of all Canadian landings since 1992 were monitored at dockside. Canadian catches since 1995 have usually been below the quota due to closure of some fleet sectors when the cod quotas were reached. At-sea observers monitored $98 \%$ of otter trawl and $8 \%$ of longline landings by weight in 2007. Discarding and misreporting of haddock by the groundfish fishery have been negligible since 1992.

Between 1994 and 2004, the Canadian fishery for groundfish was not permitted from 1 January to 30 May. In 2005, increasing haddock abundance led to an exploratory Canadian groundfish fishery in January and February that was continued in 2006 and 2007. So as not to adversely affect the rebuilding of cod on EGB, the exploratory winter fishery was closed (February 15 in 2007) when it was determined that cod were actively spawning, i.e. when $30 \%$ of cod were in the spawning or post-spawning stages.

In recent years, the Canadian fishery has been conducted primarily by vessels using otter trawls and longlines with some handlines and gillnets. In 2007, 99\% of the catch was taken by tonnage
class 1, 2 and 3 (less than 150 tons) vessels, corresponding roughly to vessels less than 65 ft in overall length. Otter trawls took 84\% of the haddock and longliners took 16\% (Table 3). The highest monthly catches in 2007 occurred in July followed by August, September and June ( $26 \%, 21 \%, 16 \%$ and $12 \%$, respectively) (Table 4, Figure 4). The winter fishery accounted for $13 \%$ of the landings.

Canadian landings until 1995 include those catches reported by the scallop fishery, but, since 1996, this fishery has been prohibited from landing haddock and this species is discarded. Landings of haddock by the scallop fleet have been low (Table 3) with a maximum of 38 mt reported in 1987. Discards of haddock ranged between 29 and 186 mt since 1969 (Van Eeckhaute et al. 2005, Gavaris et al. 2007) and were estimated at 61 mt in 2007 (Table 1; Jonsen et al. 2008).

## USA

Management measures for the USA fishery have been primarily effort based since 1994; however, in 2004, quota management was introduced to regulate the USA groundfish fishery (Table 2). The USA portion of the EGB management area was closed to groundfish vessels from June 20 to Oct 19 in 2007 due to the cod catch nearing the quota. Landings by month and gear/tonnage class for 1969 to 1993 are slightly different than what was reported in previous assessments as they were recalculated using a standard algorithm for estimating landings by statistical area (Palmer 2008). USA landings of EGB haddock in 2007 were derived from mandatory fishing vessel logbooks and dealer reports. A new system was used to allocate landings for 1994-2007 and is described in (Wigley et al. 2008).

Groundfish fishery discards were estimated from observer samples by taking the quarterly ratio of kept to discarded haddock. Each quarterly ratio was then raised by total landed haddock per quarter. This differs from the method used to estimate discards for the assessment of Georges Bank as a whole, where the ratio of kept haddock to discards of all species was used (see Wigley et al. 2007 for ratio estimator details). Due to the low number of observed trips to EGB, and the fact that the observed trips only span the years 1989-present, the existing discard estimation (ratio of kept:discarded haddock) was applied to maintain consistency with the existing time series of discards in the assessment. In the future, it would be worthwhile to explore whether the two methods produce similar scales of discard estimates.

USA catches of EGB haddock increased in 2007 to 729 mt compared to the 2006 catch of 591 mt . The 2007 USA catch quota was $6,270 \mathrm{mt}$ (Table 1); as in 2005 and 2006, the 2007 catch was constrained by the low cod quota. Landings accounted for 247 mt . The majority of USA landings occurred in quarter 2 (72\%) and quarter 4 (25\%). Landings were very low for quarters 1 and 3 (Table 5). As in other years, the otter trawl gear accounted for the majority of the USA landings ( 230 mt ). The contribution by other gear ( 16 mt ) was $6 \%$ (Table 6).

USA discards from the otter trawl fishery increased from 146 mt in 2006 to 482 mt in 2007. Discards from this fleet had been relatively low in recent years due to high trip limits and larger trawl mesh size but, in 2007, 66\% (by weight) of the haddock catch was discarded, an increase from 2004, 2005 and 2006 when discards accounted for $8 \%, 10 \%$ and $25 \%$, respectively, of the USA catch. Most of the discards, 428 mt (89\%), occurred in quarter 4 (Table 7). To mitigate the discarding of haddock, the minimum legal size was decreased in August 2007 from 48.2 cm (19") to 45.7 cm (18"). The discards from the scallop fleet were not available but have been negligible in the past.

## Size and Age Composition

## Canadian

The size and age composition of haddock in the 2007 Canadian groundfish fishery was characterized using port and at-sea samples from all principal gears and seasons (quarters) (Table 8). For trips that were sampled by both at-sea observers and port samples, the length frequencies were combined to ensure that samples were used in a consistent manner. The size composition of haddock discards in the 2007 Canadian scallop fishery was characterized by quarter using length samples obtained from 14 observed scallop trips (Table 8). The 2007 DFO survey ages, augmented with port samples, were applied to the first quarter length composition and fishery age samples for quarters 2, 3 and 4 were applied to the corresponding length compositions for both the groundfish fishery and discards.

The modal length of landings in the Canadian fisheries was 46.5 cm for otter trawlers and longliners (Figure 5). The winter fishery caught larger fish, with a mode at 52.5 cm (Figure 6). Gill-netters caught few haddock. The percentage of haddock below 43 cm decreased slightly from $10 \%$ in 2006 to $9 \%$ in 2007. The scallop dredge discards mode was 42.5 cm .

## USA

USA landings of EGB haddock are divided into "large" and "scrod" market categories for sale purposes. Landings of large haddock totaled 47 mt and scrod haddock totaled 199 mt in 2007 (Table 7). Length samplings for USA EGB landings in 2007 were limited and were available only for quarters 1, 2 and 4. All market/quarter categories, except for "unclassified", were augmented with lengths from adjacent unit areas 522 ( 5 Zh ) and 525 ( 5 Zn ). Age sampling was similarly distributed with a total of 235 ages. There was only 1 age sample of 50 fish available for the "large" category so the landings for large could only be estimated at an annual level. There were a few more samples for scrod (3 samples for each half-year) so the scrod landings at age could be estimated semi-annually but not quarterly. Due to the low level of sampling, and with the majority of the landings in quarter 2, an annual age-length key was applied to the USA landings and the resultant landings at age were assigned to quarter 2 (Table 9).

USA fishermen are required to discard haddock under the legal size limit. US discards at age of Georges Bank haddock for calendar year 2007 in statistical areas 551, 552, 561 and 562 (Eastern Georges Bank, EGB) were estimated quarterly from at-sea observer data. Due to low sampling, length frequencies in the EGB were augmented with samples from the adjacent areas of 522 and 525. As most of the discarding was due to the otter trawl fleet, length samples from remaining gears were scant (hook, gillnet, and 'other'). Available length frequencies were compared by gear, and both the range of observations, and the modal length, appeared similar. Therefore, length samples were combined across gears. The resulting combined length frequencies by quarter were converted to discarded number at age (Table 9) by applying the spring (quarters 1 and 2) or fall (quarters 3 and 4) NMFS bottom trawl survey age length key. Discarded numbers at age were converted to discarded weight at age by quarter by taking the product of the number at length by the weight at length by the age length key by quarter. Total estimated US discards on EGB in calendar year 2007 were 482 mt . The total number of observed trips decreased to 17 in 2007, down from 54 observed trips on EGB in 2006.

The length composition of USA landings were bimodal at 48.5 cm with a smaller mode at 56 cm . The discards mode was at 46.5 cm (Figure 7).

Ages of survey and commercial-caught haddock were separately assigned by the DFO and the NMFS age readers, L. Van Eeckhaute and S. Sutherland, respectively. Inter-reader agreement testing between the NMFS and DFO labs was completed and intra-reader testing was undertaken at the NMFS lab. High agreement was attained, indicating that age determinations at both labs continue to be reliable (Table 10, http://www.nefsc.noaa.gov/fbi/QA-QC/ageresults.html). Age reader agreement was judged to be satisfactory for estimating catch at age.

The 2007 Canadian and USA landings and discards at age estimates by quarter (Table 9) were summed to obtain the combined quarterly and annual catch at age (Table 11 and Figure 8) and appended to the 1969-2006 catch at age data (Van Eeckhaute et al. 2007). The age composition of the catch projection made in 2006 for 2007 agrees well with the observed (Figure 9). Average Canadian fishery weights and lengths at age are summarized in tables 12 and 13, and Figure 10. The 2003 year class (Age 4) dominated the fishery in 2007. USA discards represented $73 \%$ by numbers of the USA catch, but only $5 \%$ by numbers of the combined Can/USA catch. Most of the USA discards were Age 4, i.e., 2003 year class.

The dominant age group in the fishery has increased from ages 2 and 3 during earlier periods to Age 4 in 1995 to 2004 due primarily to a change in mesh type and an increase in mesh size (Table 2). The 2005 to 2007 age composition reflects its domination by the 2000 and 2003 year classes. The age composition during the 1969 to 1974 period was atypical since it was dominated by the outstanding 1962 and 1963 year classes which continued to contribute substantially at ages 6 and older (Figure 11).

## ABUNDANCE INDICES

## Research Surveys

Surveys of Georges Bank have been conducted by DFO each year (February/March) since 1986 and by NMFS each fall (October/November) since 1963 and each spring (April) since 1968. All surveys use a stratified random design (figures 12 and 13). For the NMFS surveys, two vessels have been employed and there was a change in the trawl door type in 1985. Vessel and door type conversion factors (Table 14), derived experimentally from comparative fishing, have been applied to the survey results to make the series consistent (Forrester et al. 1997). Additionally, two different trawl nets have been used on the NMFS spring survey, a modified Yankee 41 during 1973-81 and a Yankee 36 in other years, but no conversion factors are available for haddock.

The Alfred Needler is the standard vessel used for the DFO Georges Bank survey, but, due to unavailability of the Needler, the Wilfred Templeman, a sister ship to the Needler, has been used in several years, 1993, 2004, 2007 and again in 2008. No conversion factors are available for the Templeman, however, this vessel is considered to be similar in fishing strength to the Needler. In 2008, the DFO survey was delayed and took place in March over a 3 week period.

The spatial distribution of catches by age group (1, 2, and 3+ for spring and 0, 1 and $2+$ for fall) for the most recent surveys is shown in comparison to the average distribution over the previous 10 year period (figures 14, 15 and 16). Ages $2+$ in the NMFS 2007 fall survey were found on the northern edge in large numbers similar to the 10-year average distribution. The 2008 DFO survey found adult fish (ages $3+$ ) abundant and widely distributed on the Canadian side of the bank with some large catches in 5Zm on the USA side near the Canada/USA border. A month later, during the NMFS spring survey, adult fish were found in large quantities on the US side as well as the Canadian side, a distribution pattern which has been persistent from year to year.

Catches of the 2006 year class were low for all three surveys. Catches of the 2007 year class were also low and were more abundant on the southern part of the bank.

Age-specific, swept area abundance indices show that the three surveys are consistent and track year class strengths well (tables 15, 16 and 17; Figure 17). Some year effects are evident. For example, low spring catches occurred in both the 1997 DFO and NMFS surveys. Survey adult biomass indices (ages 2-8 in fall; 3-8 in spring) peaked during the early 1960s (Figure 18). After declining to a record low in the early 1970s, they peaked again in the late 1970s, though at a lower level, and again during the mid to late 1980s at about half the level of the 1970s peak. Adult biomass generally increased during the 1990s and 2000s. Since about 2003, the adult biomass indices have seen significant fluctuation with a large decrease in 2008 for the NMFS spring survey, an increase in the 2007 NMFS fall survey and the 2008 DFO survey.

All three survey series indicate that the 2003 year class is one of the strongest on record with the Age 5 indices for the spring surveys and the Age 4 index for the fall survey the highest for those series for those ages. The three new survey observations for the 2006 year class are all lower than the previous year's values (Figure 19). First indications for the 2007 year class indicate that it may be better than the 2001, 2002 and 2006 year classes.

## GROWTH

Canadian fishery weights at age (Table 12, Figure 10) in 2007 increased for ages 1 to 4, but, decreased for ages 5 to 8 . In 2008, DFO survey weights at age (Table 18 and Figure 10) and lengths at age (Table 19 and Figure 20) increased for ages 1 to 4, and Age 7, interrupting a downward trend that started after the mid-1990s for the older ages and around 2001 for the younger ages. Weights for ages 5 and 8, the dominant year classes, decreased. Average size at age has declined substantially so that haddock of Age 3 and older are now at or smaller than the size that the next younger age group was in previous years before the declines occurred. However, the 2007 year class average survey weight and length at Age 1 are at the level that was seen in earlier years.

Weights at age from the DFO survey are considered beginning of year population weights and are calculated using the method described in Gavaris and Van Eeckhaute (1998) in which weights observed from the survey are weighted by population numbers at length and age. Fishery weights are derived from the lengths using a length-weight relationship (Waiwood and Neilson 1985).

## HARVEST STRATEGY

The Transboundary Management Guidance Committee (TMGC 2003) has adopted a strategy to maintain a low to neutral risk of exceeding the fishing mortality limit reference, $\mathrm{F}_{\text {ref }}=0.26$. When stock conditions are poor, fishing mortality rates should be further reduced to promote rebuilding.

## ESTIMATION OF STOCK PARAMETERS

## Calibration of Virtual Population Analysis (VPA)

Tuned virtual population analysis was used to estimate stock parameters. The adaptive framework, ADAPT, (Gavaris 1988) was used to calibrate the virtual population analysis with the research survey data. Details of the model formulations and model assumptions can be found in Gavaris and Van Eeckhaute (1998) with the following modifications: 1) an annual catch at age instead of a quarterly catch at age, 2) revised survey timing, and 3) change in ages used to estimate oldest age F. The survey timing was revised from what was used in previous assessments to include recent years in the calculation as follows: DFO spring from 0.16 to 0.17 , NMFS spring from 0.29 to 0.28 and the NMFS fall survey from 0.69 to 0.79 . The large fall survey change was mainly due to an error in the previous calculation. The effects of these two changes on population numbers and $4+\mathrm{F}$ are negligible and are illustrated in Appendix A , figures A1 to A4. An increase in the age at full recruitment to the fishery was observed from 2003 onward which prompted a change in the ages used to calculate $F$ on the oldest age (Age 8). Figure 21 illustrates the relationship between Age 4 and Age 5 within the same year class for numbers caught and for fishing mortality. Both catch and F show a decrease in Age 4 catch and F relative to Age 5 for 2003 to 2006. Therefore, oldest age F for 2003 to 2007 was calculated using the average weighted $F$ on ages 5 to 7 instead of ages 4 to 7 , as was done in previous assessments.

The VPA was based on an annual catch at age, $C_{a, t}$ for ages $a=0,1,2 \ldots 8,9+$, and time $t=1969,1970 \ldots 2007$ where $t$ represents the beginning of the time interval during which the catch was taken. Catch at age 0 (i.e., discards) was included in the catch at age. The population was calculated to the beginning of 2008. The VPA was calibrated to bottom trawl survey abundance indices, $I_{s, a, t}$ for
$s=$ DFO, ages $a=1,2,3 \ldots 8$, time $t=1986.17,1987.17 \ldots 2007.17,2008.00$
$s=$ NMFS spring (Yankee 36), ages $a=1,2,3 \ldots 8$, time $t=1969.28$ 1970.28, $\ldots 2007.28$,
2008.00
$s=$ NMFS spring (Yankee 41), ages $a=1,2,3 \ldots 8$, time $t=1973.28,1974.28 \ldots 1981.28$
$s=$ NMFS fall, ages $a=0,1,2 \ldots 5$, time $t=1969.79,1970.79 \ldots 2007.79$. Since the population is calculated to beginning year 2008, the NMFS and DFO spring surveys in 2008 were designated as occurring at time 2008.00. Other details of the tuning setup were the same as those used in the previous assessments and can be found in Van Eeckhaute et al. 2007.

Statistical properties of estimators were determined using conditional non-parametric bootstrapping of model residuals (Efron and Tibshirani 1993, Gavaris and Van Eeckhaute 1998). Population abundance estimates at ages 1 and 2 exhibited a large relative error of 59\% and $41 \%$, respectively, and a large relative bias at Age 1 of $13 \%$, while the relative error for other ages was between $26 \%$ and $32 \%$ with a relative bias between $1 \%$ and $6 \%$ (Table 20). While trends in the three surveys are generally consistent, the survey indices exhibit high variability and the average magnitude of residuals is large relative to other assessments. Although several large residuals were apparent, these do not appear to have a substantial impact on estimates of current abundance (figures 22-26). Some patterns in the residuals (by cohort and by age) suggest year class and/or year effects.

## Retrospective Analysis

Retrospective analyses were used to detect any patterns to consistently overestimate or underestimate fishing mortality, biomass and recruitment relative to the terminal year estimates. This stock assessment does not display a retrospective pattern. While recruitment estimates may sometimes change substantially when more data becomes available, e.g., the 1998, 2000 and 2003 year classes, successive estimates of year class abundance at age do not display any persistent tendency to be higher or lower (Figure 27). Similarly, retrospective analysis showed no persistent patterns in the estimates of adult biomass (ages 3-8) or fishing mortality (ages 4-8 weighted by population numbers) (Figure 28).

## STATE OF RESOURCE

The state of the resource was based on results from an age structured analytical assessment (VPA) that used fishery catch statistics and sampling for size and age composition of the catch (landings plus discards) for 1969 to 2007. The VPA was calibrated to trends in abundance from three bottom trawl survey series; NMFS spring, NMFS fall and DFO. For each cohort, the terminal population abundance estimates from ADAPT were adjusted for bias estimated from the bootstrap, and used to construct the history of stock status (tables 21, 22 and 23). This approach for bias adjustment was considered preferable to using potentially biased point estimates of stock parameters (O'Boyle 1998). The weights at age from the DFO survey (Table 18) were used to calculate beginning of year population biomass (Table 23). A weight of 2.4 kg , which was midway between the ages 6 and 8 weight for that cohort, was used for Age 7 in 1995 as no data were available for that age group. The 1986-95 average weight at each age was used for 1969-85.

Data to approximate the age composition of the catch from unit areas 5Zj and 5Zm during 1931 to 1955 were used to reconstruct a population analysis of EGB that was suitable for comparison of productivity.

The adult (ages $3+$ ) biomass trend compared favorably with the survey adult biomass trends (scaled with catchabilities) (Figure 29). Adult biomass increased to $38,000 \mathrm{mt}$ during the late 1970s and early 1980s due to recruitment of the strong 1975 and 1978 year classes whose abundances were estimated to be above 50 million age-1 fish each (Figure 30). However, adult biomass declined rapidly in the early 1980s as subsequent recruitment was poor and these two cohorts were fished intensely at ages 2 and 3 . Improved recruitment in the 1990s and the strong 2000 year class ( 77 million at Age 1), lower exploitation, and reduced capture of small fish in the fisheries allowed the biomass to increase from near an historical low of 9,000 mt in 1993 to $77,100 \mathrm{mt}$ in 2003. Adult biomass decreased to $54,000 \mathrm{mt}$ in 2005 but subsequently increased to $158,100 \mathrm{mt}$ ( $80 \%$ Confidence Interval: $122,300-201,100 \mathrm{mt}$, Figure 31) in 2008; higher than the 1931-1955 maximum adult biomass of about $90,000 \mathrm{mt}$. The tripling of the biomass after 2005 was due to the exceptional 2003 year class, estimated at 322.7 million Age 1 fish, the largest in the assessment time series (1931-1955 and 1969-2007). In contrast, the 2001, 2002, 2004 and 2006 year classes, at less than 8 million fish, are below the 18 million average of the 10 most recent year classes (excluding the 2003 year class). The 2005 year class ( 26.9 million Age 1 fish) is well above the 10 year average. The 2007 year class presently appears to be below-average at 13.8 million fish at Age 1.

Fishing mortality (population weighted average of fully recruited ages) fluctuated between 0.2 and 0.4 during the 1980s, and markedly increased in 1992 and 1993 to about 0.6, the highest observed (Table 22, Figure 32). From 2003 onwards, the age at full recruitment into the fishery
has been at Age 5 (rather than Age 4 as in previous years) due to a decline in size at age of haddock. Fishing mortality (ages 4+ for pre-2003 and ages $5+$ for 2003 onwards) was below $\mathrm{F}_{\text {ref }}=0.26$ during 1995 to 2003, above $\mathrm{F}_{\text {ref }}$ during 2004 to 2006, but in 2007 declined to 0.14 ( $80 \%$ Confidence Interval: 0.11 - 0.18, Figure 31). The determination of $F_{\text {ref }}$ was based on analyses that assumed full recruitment to the fishery for ages 4 and older.

The partial recruitment at age for EGB haddock has decreased in recent years (Table 24 and 25; Figure 33) and, consequently, fishing mortality based on ages $5+$, as fully recruited, has been consistently higher than F for ages $4+$ since 2003 (Figure 32). This is most noticeable for 2004 and 2007, years when the large 2000 and 2003 year classes were Age 4 and had a large effect on the $4+\mathrm{F}$. Lower weights at age have resulted in a reduced partial recruitment so that Age 4 is now no longer fully recruited to the fishery. Therefore, partial recruitment estimates for ages 1 to 4 for recent years are more appropriately normalized on ages 5-8 (Table 25). Due to the magnitude of the 2003 year class, the partial recruitment pattern used for this year class will have a significant impact on the estimates of the magnitude and composition of future catches.

Gains in fishable biomass may be partitioned into those associated with somatic growth of haddock which have previously recruited to the fishery, and those associated with new recruitment to the fishery (Rivard 1980). We used Age 2 as the age of first recruitment to the fishery. This choice facilitated comparisons with historic stock productivity but may be less representative of the current fishery selectivity. Since 1993, except for 1996, 2001, 2003 and 2004, surplus production (biomass gains from growth and from recruitment, decremented by losses due to natural deaths) has exceeded fishery harvest yields, resulting in net population biomass increases (Figure 34). Growth of fish is the dominant component of the biomass gain but recruitment accounts for significant portions when stronger year classes enter the population, e.g. the 2000 year class in 2002 and the 2003 year class in 2005 (Figure 35). The biomass contributed by the 2003 year class, both when it recruited at Age 2 and through growth during that year was greater than that of any other previous cohort since 1969.

## PRODUCTIVITY

Recruitment, as well as age structure, spatial distribution and fish growth reflect changes in the productive potential.

Recruitment, while highly variable, has generally been higher when adult biomass has been above 40,000 mt (Figure 36). Since 1969, only the 1975, 1978, 2000 and 2003 year classes have been above the average abundance of year classes observed during the period 1931-55. The recruits per adult biomass ratio was generally low during the 1980s but higher during the 1990s, comparable to that in the 1931-1955 period (Figure 37), when the $3+$ biomass was above 40,000 mt. Since 2001, with the exception of 2003 and 2005, recruits per spawner have again been low.

In both absolute numbers and percent composition, the population age structure displays a broad representation of age groups (Figure 38), reflecting improving recruitment and lower exploitation, particularly at younger ages, since 1995.

The spatial distribution patterns observed during the most recent bottom trawl surveys were similar to the average patterns over the previous ten years. Consistent with the pattern observed for previous exceptional year classes, the 2003 year class, the main component of the $3+$ age group, was widely distributed throughout the survey area (figures 14, 15 and 16).

DFO survey average weights at length, used to reflect fish condition, exhibit a declining trend since the late 1990s (Figure 39). A reduction was again observed during 2007. Both length and weight at age have generally declined since about 2000. While size at age increased in 2008 for the younger age groups, weights remained below the 1991 to 2000 average (Table 18). The size at age for the 2003 year class is smaller than previous year classes, but its rate of growth at length is similar to previous year classes (Figure 40).

In summary, with expanded age structure, broad spatial distribution and improved recruitment, resource productivity is currently high, hindered only by the recent reductions in fish size at age.

## OUTLOOK

This outlook is provided in terms of consequences with respect to the harvest reference points for alternative catch quotas in 2009. Uncertainty about standing stock generates uncertainty in forecast results which is expressed here as the risk of exceeding $\mathrm{F}_{\text {ref }}=0.26$. The risk calculations assist in evaluating the consequences of alternative catch quotas by providing a general measure of the uncertainties. However, they are dependent on the data and model assumptions and do not include uncertainty due to variations in weight at age, partial recruitment to the fishery, natural mortality, systematic errors in data reporting or the possibility that the model may not reflect stock dynamics closely enough. To characterize the dependence of the projection results on the fishery partial recruitment for the 2003 year class, a sensitivity analysis was performed to augment the risk analysis.

For the projection and risk assessment, for values which did not involve the 2003 year class the following inputs were used. The average DFO survey weights at age for the three most recent years (Table 18) were used for beginning year population weights. Average fishery weights at age for the three most recent years (Table 12) were used for fishery weights. For the partial recruitment, the average fishery partial recruitment for the most recent five years was used (Table 29).

As in the previous assessment for this stock, the 2003 year class will comprise a large portion of the catch for the projected year, 2009. Predictions of weights at age and partial recruitment for this year class used for input into the risk assessment and projection are very influential. Inputs for population and fishery weights for the 2003 year class were derived by accounting for recent trends in reduced growth rate as demonstrated by the 1998, 1999 and 2000 year classes (Figure 41), as was done for the 2006 and 2007 assessments (Van Eeckhaute and Brodziak 2006, Van Eeckhaute et al. 2007). Data points at younger ages were excluded as the addition of these points changed the functional relationship from linear to curvilinear. The predicted growth rate at length was applied to the 2008 DFO survey average length for the 2003 year class (45.7 cm at Age 5) to obtain the beginning of year length at Age 6, i.e. L6=L5 x $e^{\text {growth rate }}$, and then sequentially, at Age 7 using the growth rate predicted for the length at Age 6 (Table 26). Average fishery lengths were determined from the relationship between beginning year length (from the DFO survey) and the fishery length in the same year using data from 1995 to 2006, when the Canadian mobile gear fishery was using square mesh after having use diamond mesh previously. (Figure 42). The resulting 2003 year class predicted lengths used for the population and fishery are compared to other year classes in Figure 43. The length estimates were then converted to weights using the length weight relationship used to convert the Canadian fishery lengths to weights (Waiwood and Neilson 1985). Beginning of year weights at age were reduced by $10 \%$ to account for the reduction in observed weights relative to those derived from the length weight relationship (Table 27). Weights at age for the fishery, derived from the length
weight relationship, were considered appropriate as this relationship is based on fishery data (Table 28).

The relationship between partial recruitment values and fishery weights, which reflect fishery lengths, was used to determine partial recruitment values. The Canadian groundfish fishery switched from diamond mesh to square mesh around 1995 so data from 1995 to 2007 were used to determine this relationship (Figure 44). A drop in Age 4 partial recruitment compared to Age 5 is observed after 2002 (Table 24). Therefore, the 1995 to 2002 partial recruitment values were based on ages 4-8 as fully recruited while the 2003 to 2007 values were based on ages 58. Values of 0.58 for Age 5 in 2008 and 0.83 for Age 6 in 2009 were judged to be appropriate for the 2003 year class for the catch projection.

Stock size estimates at the beginning of 2008 were used to start the forecasts. Abundances of the 2008 and 2009 year classes were assumed to be 20 million at Age 1, which is near the previous 10-year average (2003 year class excluded). Natural mortality was assumed to be 0.2.

A risk assessment was conducted to beginning year 2010 which incorporated these patterns in growth and partial recruitment (Table 29). Assuming a 2008 catch equal to the $23,000 \mathrm{mt}$ total quota, a combined Canada/USA catch of $33,000 \mathrm{mt}$ in 2009 results in a neutral risk (50\%) that the 2009 fishing mortality rate would exceed $\mathrm{F}_{\text {ref }}=0.26$ (Figure 45) and adult biomass is projected to be $131,000 \mathrm{mt}$ at the beginning of 2010 (Table 30). A catch of $28,000 \mathrm{mt}$ in 2009 results in a low risk (25\%) that the 2009 fishing mortality rate will exceed $\mathrm{F}_{\text {ref. }}$. The 2003 year class is expected to constitute $87 \%$ of the 2009 catch biomass. Ages 7+ are expected to account for $5 \%$ of the catch biomass, $4 \%$ by numbers.

## SPECIAL CONSIDERATIONS

While best judgment was used to determine the fishery partial recruitments for the reduced weight of the 2003 year class, the risk analysis does not capture the extent of uncertainty of the consequences for various catch levels. Using the observed range of partial recruitment at weight during 1995 to 2007, (Low=0.4-0.7, High= $0.7-0.9$ ), the 2009 projected catch could vary from $29,000 \mathrm{mt}$ to $36,000 \mathrm{mt}$. If the realized partial recruitment is near the higher end of the observed partial recruitment range (and the 2009 TAC is actually achieved), the fishery may possibly forgo available yield; if the realized partial recruitment is at the lower end, the 5+ fishing mortality could be higher than $\mathrm{F}_{\text {ref }}$.

The size at age for the 2003 year class is smaller than previous year classes, but, its rate of growth at length is similar to previous year classes. Consequently, current indications suggest that the 2003 cohort could eventually achieve a typical adult size. Size at Age 1 of the 2007 year class is similar to year classes before 2000.

Cod and haddock are often caught together in groundfish fisheries, although their catchabilities to the fisheries differ and they are not necessarily caught in proportion to their relative abundance. With current fishing practices and catch ratios, the achievement of rebuilding objectives for cod may constrain the harvesting of haddock. Modifications to fishing gear and practices, with enhanced monitoring, may mitigate these concerns.

## ACKNOWLEDGEMENTS

G. Donaldson and D. Frotten of DFO and at sea observers from Javitech Ltd. provided samples from the Canadian fishery and Sandy Sutherland provided ageing information for the USA surveys and fishery. We thank members of the fishing industry who spent time to discuss their experiences in the fishery. We also thank DFO and NMFS reviewers for their suggestions to improve the document.

| 1977-82 | Mesh size of $51 / 8^{\prime \prime}(140 \mathrm{~mm})$, seasonal spawning closures, quotas and trip limits. |  |
| 1982-85 | All catch controls eliminated, retained closed area and mesh size regulations, implemented minimum landings size ( 43 cm ). | First 5Ze assessment in 1983. |
| Oct. 1984 | Implementation of the 'Hague' line, the | undary between Canada and the USA. |
| 1985 | $5^{1 / 2 \prime \prime}$ mesh size, Areas 1 and 2 closed February-May. |  |
| 1989 |  | Combined cod-haddock-pollock quota for 4X5Zc |
| 1990 |  | EGB adopted as management unit. For mobile gear (MG) < 65 ft . - trip limits with a $30 \%$ by-catch of haddock to a maximum of 8 trips of $35,000 \mathrm{lbs}$ per trip between June 1 and Oct. 31 and 130 mm square mesh required. <br> Fixed gear required to use large hooks until June |
| 1991 | Established overfishing definitions for haddock. | MG < 65 ft similar to 1990 but mesh size increased to 145 mm diamond. |
| 1992 |  | Introduction of Individual Transferable Quotas (ITQ) and dockside monitoring. Total allowable catch $(T A C)=5000 \mathrm{mt}$. |
| 1993 | Area 2 closure in effect from Jan 1-June30. | Otter trawl (OT) fishery permitted to operate in Jan. and Feb. <br> Increase in use of square mesh. TAC $=5000$ mt. |
| 1994 | Jan.: Expanded Area 2 closure to include June and increased extent of area. <br> Area 1 closure not in effect. <br> 500 lb trip limit. <br> Catch data obtained from mandatory log books combined with dealer reports (replaces interview system). <br> May: 6" mesh restriction. <br> Dec.: Area 1,2 closed year-round. | Spawning closure extended to Jan. 1 to May 31. <br> Fixed gear vessels must choose between $5 Z$ or 4 X for the period of June to September. <br> Small fish protocol. <br> Increased at sea monitoring. <br> OT > 65 could not begin fishing until July 1. <br> Predominantly square mesh by end of year. $\mathrm{TAC}=3000 \mathrm{mt} .$ |
| 1995 |  | All OT vessels using square mesh. Fixed gear vessels with a history since 1990 of $25 t$ or more for 3 years of cod, haddock, pollock, hake or cusk combined can participate in $5 Z$ fishery. <br> ITQ vessel require at least $2 t$ of cod and $8 t$ of haddock quota to fish Georges. TAC $=2500$ mt . <br> Restrictions on catching of cod and haddock under 43 cm (small fish protocol). |
| 1996 | July: Additional Days-at-Sea restrictions, trip limit raised to 1000 lbs. | Fixed gear history requirement dropped. TAC $=4500 \mathrm{mt}$. |
| 1997 | May: Additional scheduled Days-at-sea restrictions. <br> September: Trip limit raised to $1000 \mathrm{lbs} /$ day, | Vessels over 65 ft operated on enterprise allocations, otter trawlers under 65 ft on individual quotas, fixed gear vessels $45-65 \mathrm{ft}$ |

|  | USA | Canada |
| :---: | :---: | :---: |
|  | maximum of 10,000 lbs/trip. | on self-administered individual quotas and fixed gear vessels under 45 ft on community quotas administered by local boards. TAC = $3,200 \mathrm{mt}$. |
| 1998 | Sept. 1: Trip limit raised to $3000 \mathrm{lbs} /$ day, maximum of $30,000 \mathrm{lbs} /$ trip. | Fixed gear vessels $45-65 \mathrm{ft}$ operated on individual quotas. TAC $=3,900 \mathrm{mt}$. |
| 1999 | May 1: Trip limit 2,000 Ibs/day, max. 20,000 lbs/trip. <br> Square mesh size increased to $6.5^{\prime \prime}$ <br> (diamond is 6 "). <br> June 15: Scallop exemption fishery in Closed Area II. <br> Nov. 5: Trip limit 5,000 Ibs/day, max. 50,000 lbs/trip. | TAC $=3,900 \mathrm{mt}$.; mandatory cod separator panel when no observer on board. |
| 2000 | October: Daily trip limit suspended to April 2001but retained max. trip limit of 50,000 lbs/trip. | TAC $=5,400 \mathrm{mt}$. |
| $\begin{aligned} & \hline 2001- \\ & 2002 \\ & \hline \end{aligned}$ | Day and trip limit adjustments. Daily trip limit suspended July 5, 2002. | TAC $=6,989$ and 6,740 mt for 2001 and 2002 respectively. |
| $\begin{aligned} & \hline 2002- \\ & 2003 \\ & \hline \end{aligned}$ | 30,000-50,000 lb/trip limit. <br> Trip limit suspended in Oct. 2003. | TAC $=6,933 \mathrm{mt}$ for 2003. |
| Canada - USA Resource Sharing Agreement on Georges Bank |  |  |
| 2004 | May 1, day and trip limits removed. TAC = $5,100 \mathrm{mt}$. Oct. 1: unit areas 561 and 562 closed to groundfish vessels. Nov. 19: Special Access Program (SAP) for haddock opened. Dec. 31: Haddock SAP closed. | TAC $=9,900 \mathrm{mt}$. |
| 2005 | TAC= 7,590 mt. Jan. 14: separator trawl required. | TAC $=15,410 \mathrm{mt}$; exploratory winter fishery Jan. to Feb. 18, 2005. |
| 2006 | TAC $=7,480 \mathrm{mt}$; EGB area closed to USA fishery in first half of year when USA cod quota nearly reached. | TAC $=14,520 \mathrm{mt}$; exploratory winter fishery Jan. to Feb. 6, 2006. |
| 2007 | TAC=6,270 mt. June 20: EGB area closed to USA fishery due to USA cod catch nearing quota. August 9: Minimum haddock size reduced to 18 inches October 20: EGB area opened to USA fishery. | TAC $=12,730 \mathrm{mt}$; exploratory winter fishery Jan. to Feb. 15, 2007 |

Table 3. Canadian landings (mt) of haddock from eastern Georges Bank during 1969-2007 by gear category and tonnage class for principal gears.

Table 7. United States landings and discards of haddock in 2007 by quarter and market category from eastern Georges Bank and National Marine Fisheries Service sampling intensity for lengths and ages. Numbers in bold italics indicate the number of lengths augmented from adjacent areas. Note that summaries by market category are not possible for discards as the fish are discarded at sea and are not given a market category.

| Market Category | Large | Scrod | Unclassified | Total |
| :---: | :---: | :---: | :---: | :---: |
|  | Landings (mt) |  |  |  |
| Quarter 1 | 2.92 | 3.52 | 0.12 | 6.57 |

Table 16. Total swept area estimated abundance at age (numbers in 000's) of eastern Georges Bank haddock from National Marine Fisheries Service spring surveys during 1968-2008. From 1973-81, a 41 Yankee trawl was used while a 36 Yankee trawl was used in other years. Conversion factors to adjust for changes in door type and survey vessel were applied.

Table 22. Fishing mortality rate for eastern Georges Bank haddock during 1969-2007 from a virtual population analysis using the bootstrap bias adjusted population abundance at the beginning of 2008. The aggregated rates are weighted by population numbers. The rates for ages 4+ and 5+ are also shown as exploitation rate (\%).

Figure 1. Fisheries statistical unit areas in North Atlantic Fisheries Organization Subdivision 5Ze. Alpha-numeric codes, e.g. 5Zej, are the Canadian Department of Fisheries and Oceans designations and numeric codes, e.g. 561, are National Marine Fisheries Service designations.

Figure 2. Historical catch of eastern Georges Bank haddock during 1931-1955 compared to recent catches during 1969-2007.

Figure 3. Nominal catch of eastern Georges Bank haddock during 1969-2007.

Figure 4. Haddock catches in eastern Georges Bank by month and gear for the Canadian commercial groundfish fishery in 2007 (wide bars) with sampling levels (narrow bars).

Figure 5. Catch at length by the principal Canadian eastern Georges Bank commercial haddock fisheries in 2007. In the lower graph the scallop dredge length frequency is expanded according to the axis on the right.

Figure 6. Catch at length by quarter for the Canadian eastern Georges Bank commercial haddock fisheries in 2007.

Figure 7. Catch at length of haddock by the United States eastern Georges Bank groundfish fisheries in 2007.

Figure 8. Total commercial catch at age (numbers) of eastern Georges Bank haddock during 1969-2007. The bubble area is proportional to magnitude.

Figure 9. Actual and projected 2006 eastern Georges Bank haddock catch in percent composition.

Figure 10. Average weights at age for eastern Georges Bank haddock from the Canadian commercial groundfish fishery during 1969-2007 and from the Canadian Department of Fisheries and Oceans survey during 1986-2008.

Figure 11. Age composition of the haddock catch for the eastern Georges Bank commercial fishery during 1969-1974, 1975-1984, 1985-1994, 1995-2004, and 2005-2007.

Figure 12. Stratification scheme used for National Marine Fisheries Service surveys. The eastern Georges Bank management area is indicated by shading.

Figure 13. Stratification scheme used for the Canadian Department of Fisheries and Oceans survey. The eastern Georges Bank management area is indicated by shading.

Figure 14. Distribution of eastern Georges Bank haddock abundance (number/tow) as observed from the National Marine Fisheries Service fall survey. The squares (left panels) are shaded relative to the average catch for 1997 to 2006. The expanding symbols (right panels) represent the 2007 survey catches

Figure 15. Distribution of eastern Georges Bank haddock abundance (number/tow) as observed from the Canadian Department of Fisheries and Oceans survey. The squares (left panels) are shaded relative to the average catch for 1998 to 2007. The expanding symbols (right panels) represent the 2008 survey catches.

Figure 16. Distribution of eastern Georges Bank haddock abundance (number/tow) as observed from the National Marine Fisheries Service spring survey. The squares (left panels) are shaded relative to the average catch for 1998 to 2007. The expanding symbols (right panels) represent the 2008 survey catches.

Figure 17. Estimated abundance at age (numbers in 000's) of eastern Georges Bank haddock for the Canadian Department of Fisheries and Oceans (DFO), National Marine Fisheries Service (NMFS) spring and NMFS fall surveys during 1963-2008. Bubble area is proportional to magnitude (see Tables 14-16). Conversion factors to adjust for changes in door type and survey vessel were applied to the NMFS surveys. From 1973-81 (pale circles), a 41 Yankee trawl was used for the NMFS spring survey while a 36 Yankee was used in the other years. Symbol size has not been adjusted between surveys for the catchability of the survey.

Figure 18. Biomass from National Marine Fisheries Service (NMFS) fall (ages 2-8), NMFS spring (ages 3-8) and Canadian Department of Fisheries and Oceans (DFO) (ages 3-8) research surveys (scaled by calibration constants) for eastern Georges Bank haddock during 1963-2008.

Figure 19. Year-class abundance for ages 0 and 1 from the National Marine Fisheries Service (NMFS) fall survey and ages 1 and 2 from the NMFS spring and Canadian Department of Fisheries and Oceans (DFO) research surveys (scaled by calibration constants) for eastern Georges Bank haddock during 1963-2008.

Figure 20. Length at age for eastern Georges Bank haddock derived from Canadian Department of Fisheries and Oceans surveys during 1986-2008.

Figure 21. Relationship between Age 4 and Age 5 (from same year class) catch and fishing mortality (F) for eastern Georges Bank haddock for 1969 to 2006.

Figure 22. Residuals by year and age group for Canadian Department of Fisheries (DFO) and National Marine Fisheries Service (NMFS) research survey indices during 1969-2008 for eastern Georges Bank haddock. Solid symbols indicate positive values, open symbols indicate negative values. Bubble area is proportional to magnitude. From 1973-81 (pale circles), a 41 Yankee trawl was used for the NMFS spring survey while a 36 Yankee was used in the other years.

Figure 23. Age by age plots of the observed and predicted In abundance index versus In population numbers for eastern Georges Bank haddock from the Department of Fisheries and Oceans survey during 1986-2008.

Figure 24. Age by age plots of the observed and predicted In abundance index versus In population numbers for eastern Georges Bank haddock from the National Marine Fisheries Service spring survey with a Yankee 36 net during 1969-1972 and 1982-2008.

Figure 25. Age by age plots of the observed and predicted In abundance index versus In population numbers for eastern Georges Bank haddock from the National Marine Fisheries Service spring survey with a Yankee 41 net during 1973-1981.

Figure 26. Age by age plots of the observed and predicted In abundance index versus In population numbers for eastern Georges Bank haddock from the National Marine Fisheries Service fall survey 19692007.

Figure 27. Retrospective estimates of eastern Georges Bank haddock year-class abundance as additional years of data were included in the assessment did not display any persistent trends.

Figure 28. Retrospective estimates from virtual population analysis of eastern Georges Bank haddock biomass and fishing mortality as successive years of data were excluded in the assessment.

Figure 29. The eastern Georges Bank adult haddock (ages 3+) biomass trend from virtual population analysis compared with the survey adult biomass (scaled with catchabilities) trends.

Figure 30. Beginning of year adult (3+) biomass and number of Age 1 recruits for eastern Georges Bank haddock during 1931-1955 and 1969-2008.

Figure 31. Confidence distribution with 80\% confidence intervals for 2008 eastern Georges Bank haddock ages $3+$ biomass ( 000 mt ) and 2007 ages 5+ fishing mortality.

Figure 32. Fishing mortality rate (weighted by population) for eastern Georges Bank haddock ages 4+ and 5+ during 1969-2007 and the fishing mortality threshold reference established at $\mathrm{F}_{\text {ref }}=0.26$.

Figure 33. Average partial recruitment of eastern Georges Bank haddock for 3 year classes, 1998, 2000 and 2003 and the average for 2003 to 2007. The partial recruitment is normalized to ages $4-8$ for years before 2003 and to ages 5-8 for years after 2002.

Figure 34. Surplus production of eastern Georges Bank haddock available to the commercial fishery compared to the harvested yield during 1969-2007.

Figure 35. Amount of productivity attributible to growth (ages 2 to $9+$ ) of eastern Georges Bank haddock and the amount contributed by recruitment (Age 2) during 1969-2007.

Figure 36. Relationship between eastern Georges Bank adult (ages 3+) haddock biomass and recruits at Age 1 during 1931-1955 and 1969-2007.

Figure 37. Ratio of recruits (numbers at Age 1) to spawning biomass (kg) for eastern Georges Bank haddock during 1931-1955 and during 1969-2007.

Figure 38. The age composition and absolute abundance at age of the eastern Georges Bank haddock population in 2008 compared to averages during 1931-1955, 1969-1974, 1975-1984, 1985-1994, and 1995-2005.

Figure 39. Canadian Department of Fisheries and Oceans survey weights at lengths for eastern Georges Bank haddock for six 2 cm length groupings during 1986-2008.

Figure 40. Growth of eastern Georges Bank Georges Bank haddock year classes.

Figure 41. Relationship between length and growth rate derived for eastern Georges Bank haddock using observed growth increments from the 1998, 1999 and 2000 year classes.

Figure 42. Relationship between eastern Georges Bank haddock beginning of year lengths (from Canadian Department of Fisheries and Oceans surveys) for 1995 to 2006 to average fishery lengths for the same year smoothed with a Loess smoothing algorithm (Clevand 1979). The lengths of the 2003 haddock year class at Age $5(45.7 \mathrm{~cm})$ and Age $6(49.4 \mathrm{~cm})$ with the corresponding fishery lengths are indicated. The 1:1 line is added for illustrative purposes.

Figure 43. Average population lengths at age and average fishery lengths at age of the 1998, 1999, 2000 and 2003 year classes of eastern Georges Bank haddock as observed from the Canadian Department of Fisheries and Oceans survey. Predicted lengths for the 2003 year class are indicated by

Figure 44. Fishery weight and partial recruitment relationship observed for eastern Georges Bank haddock in 1995 to 2007. A smoothed line was fitted to the data using a loess algorithm (Cleveland 1979). The 2003 year class predicted fishery weight at Age $5(1.533 \mathrm{~kg})$ and Age $6(1.705 \mathrm{~kg})$ with the corresponding partial recruitment ( 0.58 and 0.83 , respectively) are indicated by the dotted lines. The gray lines approximate the upper and lower range of partial recruitment values.

Figure 45. Risk of 2009 fishing mortality exceeding $F_{\text {ref }}=0.26$ for eastern Georges Bank haddock for increasing catch quotas.

Appendix A. Modifications to ADAPT formulation from that used in previous assessment (2007).

Figure A1. Comparison of eastern Georges Bank haddock population numbers (1+) for ADAPT formulations using a quarterly catch at age (Q CAA) versus an annual catch at age (Annual CAA).

Figure A2. Comparison of 4+ weighted fishing mortality for eastern Georges Bank haddock for ADAPT formulations using a quarterly catch at age (Q CAA) versus an annual catch at age (Annual CAA).

Figure A3. Comparison of eastern Georges Bank haddock population numbers (1+) for ADAPT formulations using an annual catch at age (Annual CAA) versus the same formulation but with revised survey timing.

Figure A4. Comparison of eastern Georges Bank haddock 4+ fishing mortality for ADAPT formulations using an annual catch at age (Annual CAA) versus the same formulation but with revised survey timing.

[^0]:    ${ }^{1} 1895 \mathrm{mt}$ excluded because of suspected area misreporting.

[^1]:    ${ }^{2}$ Total includes catches for tonnage classes which are not listed, only tonnage classes with substantial catches listed
    ${ }^{2}$ Catches of 26 t , 776t, 1091t and 2 t for side otter trawlers and stern otter trawlers tonnage classes 2,3 and 5 respectively were excluded because of suspected area misreporting.
    ${ }^{3}$ Tonnage class 1 landings included in 'Total'. Historically, tonnage class 1 accounted for a low proportion of total otter trawl landings but the proportion has increased in recent years..

[^2]:    ${ }^{1}$ Catches of $3 t, 1846$ t and 46 t for Jan., Feb., and Mar., respectively for otter trawlers were excluded because of suspected area misreporting

[^3]:    ${ }^{1}$ Discards from the scallop fishery were estimated by quarter.
    ${ }^{2}$ Two dredge samples borrowed from April DR.
    ${ }^{3}$ Combined with August GN
    ${ }^{4}$ Two dredge samples borrowed from Sept DR.
    ${ }^{5}$ Ages for 5 length groupings were estimated and are not included in the total.
    ${ }^{6}$ Ages for 2 length groupings were estimated and are not included in the total.
    ${ }^{7}$ Ages for 8 length groupings were estimated and are not included in the total.
    ${ }^{8}$ Ages for 6 length groupings were estimated and are not included in the total.
    ${ }^{9}$ Otoliths were not available for some lengths. Ages at these lengths with no otoliths sampled were estimated by comparing to other quarters and year class strengths.

[^4]:    ${ }^{1}$ One haddock measured
    ${ }^{2}$ Excludes 2005 value.

[^5]:    ${ }^{1}$ One haddock measured.
    ${ }^{2}$ Excludes 16.5 cm value in 2005.

[^6]:    ${ }^{1}$ Observed 2008 beginning year length for 2003 year class from the Canadian Department of Fisheries and Oceans survey
    ${ }^{2}$ length $_{a+1}=$ length $_{a} x e^{\text {growth rate }}$
