#### Abstract

Combined Canada/USA catches averaged 17,508 mt between 1978 and 1992. They peaked at $26,463 \mathrm{mt}$ in 1982, declined to $1,684 \mathrm{mt}$ in 1995, fluctuated around $3,000 \mathrm{mt}$ until 2004 and subsequently declined again. Catches in 2009 were $1,858 \mathrm{mt}$, including 425 mt of discards. Canadian catches were 1,209 mt in 2009, whilst USA catches were 430 mt .

Adult population biomass (ages 3+) declined from about 50,000 mt in 1990 to below 10,000 mt in 1995. Since 1995 adult population biomass from the "split M 0.2" model has fluctuated between $3,200 \mathrm{mt}$ and $10,100 \mathrm{mt}$ and from the "split M 0.5 " model it has fluctuated between $5,084 \mathrm{mt}$ and $10,824 \mathrm{mt}$. It increased at the beginning of 2010 to $6,400 \mathrm{mt}$ in the "split M 0.2 " model and $9,300 \mathrm{mt}$ in the "split M 0.5 " model.

Recruitment at age 1 of 3.6 million for the 2003 year-class from the "split M 0.2 " model was similar to the 1996 year-class at age 1. Recruitment at age 1 of 5.0 million for the 2003 yearclass from the "split M 0.5 " model was the highest since the 1990 year-class but was still lower than the pre-1990 average level ( 10 million) The 2002 and 2004 year classes were the lowest on record.

Fishing mortality (F) for ages 4-9 was higher prior to 1994. Due to restrictive management measures, it declined in 1995 to $\mathrm{F}=0.36$ for the "split M 0.2 " model and 0.24 for the "split M 0.5 " model and then fluctuated until 2004. F in 2009 was estimated to be 0.33 from the "split M 0.2 " model and 0.20 from the "split M 0.5 " model. Both models show recent reductions in F since 2005; however, F has been consistently above the $\mathrm{F}_{\text {ref }}=0.18$.

Assuming a 2010 catch equal to the $1,350 \mathrm{mt}$ total quota, a combined Canada/USA catch of about $1,000 \mathrm{mt}$ ("split M 0.2 " model) and $1,400 \mathrm{mt}$ ("split M 0.5 " model) in 2011 will result in a neutral risk (50\%) that the fishing mortality rate in 2011 will exceed $F_{\text {ref. }}$. A catch of $1,850 \mathrm{mt}$ ("split M 0.2 " model) and $1,350 \mathrm{mt}$ ("split M 0.5 " model) will result in a neutral risk ( $50 \%$ ) that the 2011 adult biomass (ages 4+) will be lower than 2010. A catch of about $1,100 \mathrm{mt}$ ("split M 0.2 " model) and 450 mt ("split M 0.5" model) will result in a neutral risk (50\%) that 2012 adult biomass will not increase by 10\% from 2011.

## RÉSUMÉ

La moyenne des captures combinées du Canada et des États-Unis entre 1978 et 1992 a été de 17508 tm . Ces captures ont culminé à 26463 tm en 1982, sont tombées à 1684 tm en 1995, ont fluctué ensuite alentour de 3000 tm jusqu'en 2004, puis ont chuté de nouveau. En 2009, les captures totales étaient de 1858 tm , dont 425 tm de rejets, celles du Canada se chiffrant à 1209 t et celles des États-Unis à 430 tm .

La biomasse de la population adulte (âges 3 +) a diminué, passant d'environ 50000 tm en 1990 à moins de 10000 tm en 1995. Depuis 1995, la biomasse de la population adulte fluctue entre 3200 tm et 10100 tm selon le «modèle fractionné $M=0,2$ » et entre 5084 tm et 10824 tm selon le « modèle fractionné $M=0,5$ ». Elle a augmenté ensuite et se chiffrait au début de 2010 à 6400 tm selon le «modèle fractionné $M=0,2$ » et à 9300 tm selon le selon le « modèle fractionné $\mathrm{M}=0,5$ ».

Le recrutement à l'âge 1 de la classe d'âge 2003, chiffré à 3,6 millions de poissons selon le «modèle fractionné $M=0,2$ », était semblable à celui de la classe d'âge 1996 à l'âge 1. Selon le « modèle fractionné $M=0,5$ », ce recrutement à l'âge 1 de la classe d'âge 2003 se chiffrait à 5 millions de poissons, ce qui représente le plus fort recrutement depuis celui de la classe d'âge 1990, mais se situe encore sous la moyenne d'avant 1990 (10 millions de poissons). L'effectif des classes d'âge 2002 et 2004 était le plus bas qu'on ait connu à ce jour.

La mortalité par pêche ( $F$ ) parmi les âges 4 à 9 était plus élevée avant 1994. Elle a diminué en 1995 à $F=0,36$ selon le «modèle fractionné $M=0,2$ » et à $F=0,24$ selon le «modèle fractionné $M=0,5 »$, en raison de mesures de gestion strictes, puis a fluctué jusqu'en 2004. En 2009, elle a été estimée à 0,33 selon le «modèle fractionné $M=0,2$ » et à 0,20 selon le « modèle fractionné $M=0,5$ ». Les deux modèles dénotent des baisses de $F$ depuis 2005, mais néanmoins la mortalité $F$ s'est constamment maintenue au-dessus de $F_{\text {réf. }}=0,18$.

En supposant que les captures de 2010 soient égales au quota total de 1350 tm , des captures combinées du Canada et des États-Unis qui seraient d'environ 1000 tm (selon le « modèle fractionné $M=0,2$ ») et 1400 tm (selon le «modèle fractionné $M=0,5$ ») en 2011 se traduiraient par un risque neutre ( $50 \%$ ) que le taux de mortalité par pêche soit cette année-là supérieur à $F_{\text {réf. }}$ Des captures de 1850 tm (selon le «modèle fractionné $M=0,2$ ») et de 1350 tm (selon le «modèle fractionné $M=0,5$ ») se traduiraient par un risque neutre ( $50 \%$ ) que la biomasse des adultes (âges $4+$ ) en 2011 soit inférieure à celle de 2010. Des captures d'environ 1100 tm (selon le «modèle fractionné $M=0,2$ ») et 450 tm (selon le «modèle fractionné $M=0,5 »$ ) aboutiraient à un risque neutre ( $50 \%$ ) que la biomasse des adultes n'augmente pas de $10 \%$ en 2012 par rapport à 2011.

## INTRODUCTION

The basis and background for the delineation of management units of cod on Georges Bank and the vicinity were reviewed and summarized at the 2009 Eastern Georges Bank cod benchmark assessment meeting (O'Brien and Worcester, 2009). For the purpose of a sharing agreement and consistent management by Canada and the USA, it was decided that the transboundary management unit for Atlantic cod would be limited to the eastern portion of Georges Bank (DFO Statistical Unit Areas 5Zej and 5Zem; USA Statistical Areas 551, 552, 561 and 562) (DFO, 2002). The management area is shown in Figure 1. The USA has a requirement for management advice for the Georges Bank cod stock (5Z + Subarea 6). The status quo has been to use an assessment of cod in 5Zjm for transboundary management advice and an assessment of cod in 5Z+6 for USA domestic management advice. While other options could be followed, this option is less disruptive to the existing processes. This approach requires concurrent assessment reviews of 5Zjm and of 5Z+6 to harmonize results.

The model formulation established by the 2002 Eastern Georges Bank cod benchmark assessment (NEFSC, 2002) was used for the eastern Georges Bank cod assessment from 2002 to 2008. In recent assessments, the results exhibited a domed catchability pattern by age in both the DFO and NMFS spring surveys, and the descending limb of the fishery partial recruitment became increasingly steep for older ages. The resulting assessment generated appreciable 'cryptic' biomass that could not be observed by either the fishery or the surveys. An examination of the implications of eliminating the first quarter fishery indicated that the magnitude of those removals was not large enough to appreciably alter the annual size composition. Therefore, a marked change in fishery partial recruitment after the mid 1990s, a key feature of the 2002 benchmark model formulation, was not supported. The 2009 Eastern Georges Bank cod benchmark assessment was conducted in 2009 to address these concerns and the details of the model formulations that were agreed upon were documented in Wang et al. (2009a). The 2009 benchmark model formulation was used in the 2009 assessment (Wang et al., 2009b).

This assessment applied the 2009 benchmark formulations using Canadian and USA fishery information updated to 2009 including commercial landings and discards, the Fisheries and Oceans Canada (DFO) survey updated to 2010, the National Marine Fisheries Services (NMFS) spring survey updated to 2010, and the NMFS fall survey updated to 2009.

## FISHERY

## Commercial Fishery Catches

Historical catch data were updated at the 2009 benchmark meeting (Wang et al., 2009a). Combined Canada/USA catches averaged $17,508 \mathrm{mt}$ between 1978 and 1992. Catches peaked at $26,463 \mathrm{mt}$ in 1982, and then declined to $1,684 \mathrm{mt}$ in 1995. They fluctuated around $3,000 \mathrm{mt}$ until 2004 and subsequently declined again. Catches in 2009 were 1,858 mt, including 425 mt of discards (Table 1, Figure 2). Catches include USA and Canadian discards in all years where discard estimates were available.

Canadian catches peaked at $17,898 \mathrm{mt}$ in 1982 and declined to $1,140 \mathrm{mt}$ in 1995 (Table 1, Figure 3). Since 1995, with lower cod quotas, the fishery has reduced targeting for cod through changes in fishing practices, including the introduction of the cod separator panel for Canadian bottom trawls in 1999 and the use of the Ruhle Trawl in the USA bottom trawl fishery in 2009 (Table 2). From 1995 to 2008 Canadian catches fluctuated between 859 mt and $3,405 \mathrm{mt}$
(Table 1). In 2009 total landings including discards, were 1,209 mt against a quota of 1,173 mt, taken primarily between June and December by otter trawl and longline (Table 3, Figure 4 and 5). All 2009 landings were subject to dockside monitoring and at-sea observers monitored close to $23 \%$ by weight of the mobile gear fleet landings ( $20 \%$ of trips), $15 \%$ by weight of the fixed gear landings (15\% of trips) and 24\% of the gillnet fleet landings (8\% of trips).

Canadian regulations prohibit the discarding of undersized fish. Discards from the Canadian groundfish fishery were estimated for 1997 to 1999 (Van Eeckhaute and Gavaris, 2004) and for 2005 and 2006 (Gavaris et al., 2006, 2007a, 2007b) (Table 1). In 2007, no discards were attributed to the mobile gear fleet because of the high observer coverage (99\%) and discards for the fixed gear fleet could not be calculated because of the low observer coverage, but were assumed to be negligible as discards had not been detected in previous years (Clark et al., 2008) but discards were calculated for both fleets in the 2009 assessment (Wang et al., 2009b). As in the 2009 assessment, the ratio of sums method applied by Gavaris et al. (2006, 2007b) was used to estimate discards of cod from the 2009 Canadian groundfish fishery. Cod discards from the 2009 Canadian groundfish fishery were estimated at 22 mt from the mobile gear fleet and 115 mt from the fixed gear fleet (Table 1).

Since 1996 the Canadian scallop fishery has not been permitted to land cod. Landings until 1995 included those catches reported by the scallop fishery. Estimated discards of cod by the Canadian scallop fishery ranged up to 200 mt annually since 1978 (Van Eeckhaute et al., 2005). Estimated discards of cod by the Canadian scallop fishery were 69 mt in 2009 (Van Eeckhaute et al., 2010).

USA catches increased from $5,502 \mathrm{mt}$ in 1978 to $10,550 \mathrm{mt}$ in 1984 , then declined and fluctuated around 6,000 mt between 1985 and 1993 (Table 1, Figure 3). Since December 1994, a year-round closure of Area II (Figure 1) has been in effect, with the exception of a Special Access Program in 2004. Minimum mesh size limits were increased in 1994, 1999 and in 2002. Limits on sea days, as well as trip limits, have also been implemented (Table 2). USA catches during 1994-2000 ranged between 544 mt to $1,208 \mathrm{mt}$ and increased to $1,959 \mathrm{mt}$ in 2003. Quotas were introduced in May 2004. In 2009, USA landings increased to 430 mt ; these were the highest landings since 2004. USA landings are usually taken in the first and second quarter, but in 2009, 42\% of the landings were from quarter 2 and $31 \%$ were from quarter 3 (Figure 5).

Discards by USA groundfish fleets are permitted because of trip and size limits. In 2009, the 'Ruhle trawl', which reduces by-catch of cod, was authorized for use on eastern Georges Bank. The estimated discards of cod in the groundfish fishery for 2009 increased to 219 mt . Otter trawl gear accounted for the majority of the discards ( 218 mt ) with scallop gear accounting for the remainder (Table 1, Figure 2). Total USA catch (landings and discards combined) was 649 mt .

## Size and Age Composition

The size and age compositions of the 2009 landings by the Canadian groundfish fishery were derived from port and at-sea samples from all principal gears and seasons (Table 4, Figure 6). There are representative samples from the mobile gear fishery over all the fishing months and there was representative sampling of the fixed gear fleet for most of the fishery, except in the fourth quarter when landings were low. Comparison of port and at-sea length frequencies did not indicate any discrepancies for otter trawlers, except in November and December when there were slight differences. Fixed gear observer samples from July to September tended to have more small fish than the port samples, indicating that discarding might have occurred (Figure 7). At-sea samples were pooled with port samples to derive catch at length and age. Landings
peaked at 58 cm ( 23 in ) for bottom trawlers and 70 to 73 cm ( 28 to 30 in ) for longliners (Figure 8). Gillnetters caught fewer cod but these fish were larger, peaking at $82 \mathrm{~cm}(32 \mathrm{in})$.

The size composition of cod discards from the 2009 Canadian scallop fishery was derived from at-sea sampling. Cod discards from the scallop fishery peaked at 49 and 58 cm (19 and 23 in ). The size composition of cod discards from the groundfish fishery peaked at 58 cm (23 in) (Figure 8). The combined gear landings peaked at 49 and 58 cm (19 and 23 in ), with discards peaking at 58 cm (23 in) (Figure 9).

The size and age compositions of the 2009 USA fishery landings on eastern Georges Bank were derived using port samples from all principal gears and seasons by market category (Table 4). Landings peaked at $62 \mathrm{~cm}(25 \mathrm{in})$, and discards peaked at 53 cm (21 in) (Figure 10).

The catch composition, combined landings and discards for Canada and the USA is shown in Figure 11. Canadian and USA catches peaked at similar lengths (Canada: 58 cm (23 in); USA: $56 \mathrm{~cm}(22 \mathrm{in})$ ), but Canadian catches contained more large fish than USA catches.

Otoliths taken from port and at-sea observer samples were used for age reading. In the past, comparisons have indicated good agreement between DFO and NMFS age readers (Wang et al., 2009a). No Canada-USA age reading comparisons were available for 2009, but the intrareader comparison for the DFO reader showed good internal agreement (Table 5).

Canadian catch-at-age composition was obtained by applying quarterly fishery age-length keys to the size composition. The age-length key from the 2009 DFO survey was used to augment the first quarter key. The age composition of the USA landings was estimated by market category from length frequency and age samples pooled by calendar quarter for all gears. Discards at age from the USA groundfish and scallop fisheries (1989-2009), the Canadian groundfish fishery (1995-2009), and the Canadian scallop fishery (1978-2009) were included in the assessment.

The combined Canada/USA 2009 fishery age composition by number was dominated by the 2006 year class at age 3 (33\%), followed by the 2003 year class at age 6 (25\%) and the 2005 year class at age 4 (20\%) (Figure 12). By weight the 2003 year class still dominated the 2009 fishery (38\%) followed by the 2005 and 2006 year classes (20\%) (Figure 12). The contribution to the catch of fish older than age 7 continued to be small in recent years ( $4 \%$ by number, $9 \%$ by weight in 2009) (Table 6, Figure 13).

Fishery weights at age showed a declining trend starting in the early 1990s (Table 7, Figure 14). In 2009, the weight at age decreased for all ages except ages 2 and 4.

## ABUNDANCE INDICES

## Surveys

Surveys of Georges Bank have been conducted by DFO each year (February/March) since 1986 and by NMFS each autumn (October) since 1963 and each spring (April) since 1968. All surveys use a stratified random design (Figures 15 and 16). Most of the DFO surveys have been conducted by the CCGS Alfred Needler. A sister ship, the CCGS Wilfred Templeman, conducted the survey in 1993, 2004, 2007 and 2008 and another vessel, the CCGS Teleost, conducted 6 of the sets in 2006. No conversion factors were applied. For the NMFS surveys, two vessels have been employed and there was a change in the trawl door in 1985. Vessel and door type conversion factors derived experimentally from comparative fishing (Table 8) have
been applied to the survey results to make the series consistent (Forrester et al. 1997). Additionally, two different trawl nets have been used on the NMFS spring survey, a modified Yankee 41 from 1973-81 and a Yankee 36 in other years, but no net conversion factors were available for cod. A new vessel (FSV Henry B. Bigelow), with a different net has conducted NMFS groundfish surveys since 2009. Calibration factors by length were calculated for Atlantic cod for the data collected by the FSV Henry B Bigelow to make the data comparable to previous surveys conducted by FRV Albatross IV. The new research vessel/net combination tended to catch more cod at all lengths, but also proportionally more small cod. The calibration factors at length applied to the 2009 and 2010 NMFS spring survey and 2009 NMFS fall survey are shown in Table 9. In the past, members of the Canadian fishing industry had expressed the view that the FRV Albatross IV with the Yankee 36 net was not efficient at catching small fish. Since the new FSV Henry B. Bigelow vessel/net combination appears to catch proportionally more small fish than the Albatross, it is a concern that down-weighting the catch at length of the Bigelow surveys to match the pattern of the Albatross catches may obscure indications of recruitment of small fish. In the 2009 and 2010 NMFS spring and 2009 NMFS fall survey age 1 and 2 cod were caught but the implications of the sizes of these catches by the Bigelow to year class strength in the long term cannot be evaluated without a longer time series.

The spatial distribution of ages 3 and older cod caught during the 2010 DFO survey was similar to those observed from surveys over the previous decade with two large sets, one on the USA side close to the Hague Line and the other on the Canadian side in 5Zj (Figure 17). With the calculation of the calibration factors for cod (Table 9), the data from the NMFS 2009 and 2010 spring surveys were available for this year's assessment. The 2009 NMFS spring survey distribution of cod showed a similar distribution pattern relative to the previous decade (Figure 18), although there was only one larger tow. In 2010 the distribution was slightly different with no large tows in the northeast and one large tow to the northwest on the USA side, close to the edge of the management area (Figure 19). The distribution of cod in the NMFS fall survey was similar to previous years' surveys (Figure 20).

Total catch in numbers in the 2010 DFO survey was similar to the catch in the 2009 survey (Table 10). The 2003 year class at age 7 remained strong, at the highest level in the survey time series whilst the 2006 year class at age 5 looked promising from this survey, consistent with the previous year's survey results (Table 10, Figure 21). The 2005 year class at age 6 looked moderate, but not as strong as the 2003 year class. In the 2009 and 2010 NMFS spring surveys, the 2003 year class did not appear to be strong and the total catch in numbers continued to decrease, as it has each year since 2007 (Table 11). In the NMFS fall survey the 2006 year class at age 3 was the dominant year class in the catch (Table 12), but was not particularly strong compared to year classes in the past (Figure 21).

With the exception of the 2003 and 2006 year classes, the survey abundance at age (Tables 10-12, Figure 21) showed poor recruitment since the 1990 year class. The 2003 year class appeared strong over several ages in all surveys whilst the 2006 year class appeared promising in the DFO survey, but not in the NMFS spring and fall surveys. Compared with pre1990s, the proportion of the age composition comprised of ages 4-6 increased during the 2000s.

Biomass indices at age were calculated by applying weight at age to the abundance indices at age. Survey biomass indices have fluctuated without a clear trend in recent years. The biomass index for ages 2 to 3 has increased since 2005 with a slight decline in 2010. The biomass index for ages 4 to 6 showed a slight decreasing trend but increased for ages 7 to 8 in recent years (Figure 22).

The numbers weighted average weights at age derived from the DFO survey and NMFS spring survey were used as population weight at age for the beginning of the year. All the weights at age display a declining trend since the early 1990s, but there is some improvement in 2010 for some ages (Table 13, Figure 23). Cod condition, derived from the DFO survey and measured as average weight at length at 3 representative length groupings, showed no notable trend (Figure 24).

## HARVEST STRATEGY

The Transboundary Management Guidance Committee has adopted a strategy to maintain a low to neutral risk of exceeding the fishing mortality limit reference, $\mathrm{F}_{\text {ref }}=0.18$. When stock conditions are poor, fishing mortality rates should be further reduced to promote rebuilding.

## ESTIMATION AND DIAGNOSTICS

Evaluation of the state of the resource was based on results from an age structured analytical assessment (Virtual Population Analysis, VPA), which used fishery catch statistics and sampling for size and age composition of the catch from 1978 to 2009 (including discards). The VPA was calibrated to trends in abundance from three bottom trawl survey series: NMFS spring, NMFS fall and DFO.

Two consensus VPA model formulations were established during the benchmark assessment review in 2009 (O'Brien and Worcester, 2009; Wang et al., 2009a). These model formulations will be referred to as the "split M 0.2 " and "split M 0.5 "method in this document. The adaptive framework, ADAPT, (Gavaris, 1988) was used for calibrating the virtual population analysis with the research survey data for both the "split M 0.2 " and "split M 0.5 " formulations. Computational formulae used in ADAPT are described by Rivard and Gavaris (2003a). The data used in the model were:
$C_{a, t}=$ catch at age for ages $a=1$ to $10+$ and time $t=1978$ to 2009, where $t$ represents the year during which the catch was taken:
$I_{1, a, t}=$ DFO survey for ages $a=1$ to 8 and time $t=1986.17,1987.17 \ldots 1992.17,1993.17$
$I_{2, a, t}=$ DFO survey for ages $a=1$ to 8 and time $t=1994.17,1995.17 \ldots 2009.17,2010.00$
$I_{3, \mathrm{a}, \mathrm{t}}=$ NMFS spring survey (Yankee 41) for ages $\mathrm{a}=1$ to 8 and time $t=1978.28,1979.28$, 1980.28, 1981.28
$I_{4, \mathrm{a}, \mathrm{t}}=$ NMFS spring survey (Yankee 36), for ages $\mathrm{a}=1$ to 8 and time $t=1982.28$, 1983.28 $\ldots$ 1992.28, 1993.28
$I_{5, a, t}=$ NMFS spring survey (Yankee 36), for ages $a=1$ to 8 and time $t=1994.28,1995.28 \ldots$ 2009.28, 2010
$I_{6, \mathrm{a}, \mathrm{t}}=$ NMFS autumn survey, ages $\mathrm{a}=1$ to 5 and time $t=1978.79,1979.79 \ldots 1992.79$, 1993.79
$1_{7, a, t}=$ NMFS autumn survey, ages $a=1$ to 5 and time $t=1994.79,1995.79 \ldots 2008.79,2009.79$.

The population was calculated to the beginning of 2010.00; therefore, the DFO and NMFS spring survey indices for 2010 were designated as occurring at the beginning of the year, i.e. 2010.00. The benchmark formulations assumed that observation errors for the catch at age data were negligible. Observation errors for the abundance indices at age were assumed to be independent and identically distributed after taking natural logarithms of the values. Zero observations for abundance indices were treated as missing data as the logarithm of zero is not defined. The survey time series were split in 1993-1994. The annual natural mortality rate, M, was assumed constant and equal to 0.2 for all ages in all years for the "split M 0.2 " model formulation. For the "split M 0.5 " model formulation, M was assumed equal to 0.5 for ages $6+$ from 1994-2009 and equal to 0.2 for other ages and years. Fishing mortality on age 9 for 1978 to 2009 was assumed to be equal to the population weighted average fishing mortality on ages 7 and 8.

Estimation was based on minimization of the objective function:
$\sum_{s, a, t}\left(\ln I_{s, a, t}-\left(\hat{\kappa}_{s, a}+v_{a, t}\right)\right)^{2}$, where $s$ indexes survey.
The estimated model parameters were:
$v_{a, t}=\ln N_{a, t}=\ln$ population abundance for $\mathrm{a}=2$ to 9 at time $t=2010$
$\kappa_{1, a}=\ln$ DFO survey catchability for $\mathrm{a}=1$ to 8 at time $\mathrm{t}=1986$ to 1993
$\kappa_{2, a}=\ln$ DFO survey catchability for $\mathrm{a}=1$ to 8 at time $\mathrm{t}=1994$ to 2010
$\kappa_{3, a}=\ln$ NMFS spring survey (Yankee 41) catchability for ages $\mathrm{a}=1$ to 8 at time $\mathrm{t}=1978$ to 1981
$\kappa_{4, a}=\ln$ NMFS spring survey (Yankee 36) catchability for ages $\mathrm{a}=1$ to 8 at time $\mathrm{t}=1982$ to 1993
$\kappa_{5, a}=\ln$ NMFS spring survey (Yankee 36) catchability for ages $a=1$ to 8 at time $t=1993$ to 2010
$\kappa_{6, a}=\operatorname{In}$ NMFS autumn survey catchability for ages $\mathrm{a}=1$ to 5 at time $\mathrm{t}=1978$-1993
$\kappa_{7, a}=\ln$ NMFS autumn survey catchability for ages $\mathrm{a}=1$ to 5 at time $\mathrm{t}=1994$-2009.
Statistical properties of the estimators were determined using conditional non-parametric bootstrapping of model residuals (Efron and Tibshirani, 1993; Rivard and Gavaris, 2003a).

## A. "split M 0.2" Model

The population abundance estimate at age 9 at the beginning of 2010 exhibited the largest relative bias of $13 \%$ followed by the estimate at age 2 which showed a relative bias of $10 \%$. The relative bias for other ages/times ranged between $4 \%$ and $9 \%$. The relative error ranged between $34 \%$ and $77 \%$ (Table 14). Survey catchability (q) at age progressively increased until about age 6 for DFO 1994-2009 and age 5 for NMFS spring Y36 1994-2008 survey (Figure 25). Compared with the survey catchability prior to 1994, catchabilities for both the DFO and the NMFS spring surveys have abruptly increased starting at about age 3 . Survey catchability at age for the NMFS autumn survey was very low (Figure 25).

## B. "split M 0.5" Model

The population abundance estimate at ages 2 and 8 at the beginning of 2010 exhibited the largest relative bias of about $8 \%$, whilst for other ages/times it ranged between $3 \%$ and $7 \%$. The relative error ranged between $33 \%$ and $46 \%$ (Table 15). This model tended to have a smaller relative error than the "split M 0.2 " model for all ages except age 4 . Survey catchability (q) at age progressively increased until about age 5 for DFO 1994-2009 survey and NMFS spring Y36 1994-2008 survey, remaining flat at older ages (Figure 25). Compared with the survey catchability prior to 1994, catchabilities for both the DFO and the NMFS spring surveys have increased starting at about age 3. Survey catchability at age for the NMFS autumn survey was very low (Figure 25).

## Comparisons

The overall fit of model estimated biomass to the DFO, NMFS spring and NMFS fall surveys was generally consistent with the survey trends after 1994. In the 2009 assessment it was noted that VPA estimates at younger ages tended to be lower than survey observations in 2009, whilst VPA estimates at older ages were higher than survey observations for 2007 to 2009 (Wang et al., 2009b). This was not the case for the current assessment (Figure 26). There were still residual patterns for both models, which suggested some strong year effects (Figure 27).

Retrospective analyses were used to detect any patterns of consistently overestimating or underestimating fishing mortality, biomass and recruitment relative to the terminal year estimates. Both model formulations exhibited similar patterns, although the retrospective pattern exhibited by the "split M 0.5 " model was not quite as strong as the pattern exhibited by the "split M 0.2 " model. The 2003 and 2005 year classes were initially overestimated at age 1, whilst the 2002, 2006 and 2007 year classes were initially underestimated at age 1. There was also a tendency to initially overestimate $3+$ biomass and underestimate fishing mortality in recent years (Figures 28-29). Mohn's rho (Mohn, 1999) calculations for the "split M 02" model were 0.39 for age 1 and 0.53 for $3+$ biomass, whilst the calculations for the "split M 0.5 " model showed a rho value of 0.25 for age 1 and 0.53 for $3+$ biomass (Table 16). Retrospective adjustments to recruitment and biomass estimates would be made by applying the multiplier 1/(1+rho).

Fishing mortality from the "split M 0.5 " model was more consistent with the perception about changes in effort associated with more restrictive management measures (Figure 30). Recent management measures and observed catch better matched expectations of model output. Both models indicated flat fishing partial recruitment except for the 10+ group (Figure 31).

## STATE OF RESOURCE

Adult population biomass (ages 3+) declined substantially from about 50,000 mt in 1990 to below $10,000 \mathrm{mt}$ in 1995, the lowest observed (Table 17 and 20, Figure 32), regardless of model formulation. Since 1995, adult population biomass from the "split M 0.2" model has fluctuated between $3,200 \mathrm{mt}$ and $10,100 \mathrm{mt}$. Biomass was estimated at $6,334 \mathrm{mt}$ in 2009 and $6,394 \mathrm{mt}(80 \%$ confidence interval: $4,857 \mathrm{mt}-7,508 \mathrm{mt}$ ) at the beginning of 2010. Since 1995, adult population biomass from the "split M 0.5" model has fluctuated between 5,084 and $12,823 \mathrm{mt}$. Biomass was estimated at $9,856 \mathrm{mt}$ in 2009 and $9,260 \mathrm{mt}$ ( $80 \%$ confidence interval: $7,202 \mathrm{mt}-10,942 \mathrm{mt}$ ) at the beginning of 2010. In both models, the increase in 2006 was largely due to the recruitment of the 2003 year class, and the increases in 2007 and 2008 were due to growth of this year class (Figure 33). Lower weights-at-age in the population in recent
years, generally poor recruitment, and fishing mortality greater than $\mathrm{F}_{\text {ref }}$ have contributed to the lack of sustained rebuilding.

Recruitment at age 1 of 3.6 million for the 2003 year class from the "split M 0.2 " model was similar to the 1996 year class (Table 18, Figure 32). Recruitment at age 1 of 5.0 million for the 2003 year class from the "split M 0.5" model was the highest since the 1990 year class but was still lower than the pre-1990 average level (10 million) (Table 21, Figure 32). The 2002 and 2004 year-classes were the lowest on record. In the "split M 0.2" model the 2006 year class at age 1 at 2 million was slightly greater than half the strength of the 2003 year class at 3.6 million (Table 18). The 2006 year class at 2.4 million at age 1 from the "split M 0.5 " model was about half the strength of the 2003 year class at age 1 (5 million)(Table 21). Initial indications were that the 2008 year class is similar in strength to the 2007 and 2005 year classes, which were between $66 \%$ and $75 \%$ of the post 1990 average values from both models for recruitment at age 1.

Fishing mortality (population weighted average) for ages 4-9 was higher prior to 1994 (Tables 19 and 22, Figure 34). F declined in 1995 to $\mathrm{F}=0.36$ for the "split M 0.2 " model and to 0.24 for the "split M 0.5 " model due to restrictive management measures and then fluctuated between 0.35 and 0.84 for the "split M 0.2 " model and 0.20 and 0.55 for the "split M 0.5 " model. F in 2009 was estimated to be 0.33 from the "split M 0.2 " model and 0.20 from the "split M 0.5 " model. Both models show recent reductions in F , but fishing mortality is consistently above the reference level ( $\mathrm{F}_{\text {ref }}$ ) of 0.18 .

Yield exceeded surplus production during the early 1990s (Figure 35). Surplus production since the mid 1990s has remained considerably lower than that prior to 1990. Growth of ages 2 to 10 has typically accounted for the greatest percentage of the production. Occasionally, a strong incoming year-class at age 2 makes a greater contribution to production. The 2003 year class made such a contribution in 2005. In 2009, yield exceeded surplus production (Figure 35).

Recruitment, while highly variable, has generally been higher when ages $3+$ biomass exceeded $30,000 \mathrm{mt}$ (Figure 36). The current biomass is well below $30,000 \mathrm{mt}$. The number of recruits per spawner has not increased when the biomass has been low (Figure 37). This lack of compensation hampers stock rebuilding.

## PRODUCTIVITY

Recruitment, age structure, fish growth and spatial distribution reflect changes in the productive potential. In both absolute numbers and percent composition, the population age structure since 1995 displays a very low proportion of 7+ older age groups compared to the 1980s (Figure 38). However, in 2010 the 2003 year class does show up more strongly at age 7. Average weight at length, used to reflect condition, has been stable, but declines in length and weight at age in recent years have hampered biomass rebuilding. Size at age in the 2009 fishery continued to decline for ages 5 to 8 (Figure 39). The spatial distribution patterns observed during the most recent bottom trawl surveys showed that adult cod were distributed in a similar manner to the average over the past decade (Figures 17 to 20). Resource productivity is currently poor due to low recent recruitment and low weights at age compared to the 1980s.

## OUTLOOK

This outlook is provided in terms of consequences with respect to the harvest reference points for alternative catch quotas in 2010 (Gavaris and Sinclair, 1998; Rivard and Gavaris, 2003b). Uncertainty about standing stock generates uncertainty in forecast results which is expressed here as the risk of exceeding $\mathrm{F}_{\text {ref }}=0.18$. The risk calculations assist in evaluating the consequences of alternative catch quotas by providing a general measure of the uncertainties. However, they are dependent on the data and model assumptions and do not include uncertainty due to variations in weight at age, partial recruitment to the fishery, natural mortality, systematic errors in data reporting or the possibility that the model may not reflect stock dynamics closely enough.

For projections, the 2005 to 2009 average values were assumed for the partial recruitment pattern in 2010 to 2011. Decreasing weights at age, possible sampling problems at older ages, and peculiar growth patterns of the 2003 year class were issues for the fishery and beginning of year population weights at age. Given the importance of the 2003 year class for short-term forecasts of catch and stock size and the variations in recent growth patterns, the values for the beginning of year weights at age for ages 7,8 and 9 were determined by a regression by year class based on the weight of each year class at younger ages. Weights at ages 1 to 6 were from the recent three year average (2008 to 2010). The values for the fishery weights at age for ages 7 and 8 were also determined by a regression by year class based on the weight of each year class at younger ages whilst weights at ages 1 to 6 were from 2007 to 2009. Catch in 2010 was assumed to be equal to the $1,350 \mathrm{mt}$ quota. Projections are provided from each of the model results (Table 23).

## A. "split M 0.2" Model

Assuming a 2010 catch equal to the $1,350 \mathrm{mt}$ total quota, a combined Canada/USA catch of about $1,000 \mathrm{mt}$ in 2011 will result in a neutral risk (50\%) that the fishing mortality rate in 2011 will exceed $F_{\text {ref }}$ whereas a catch of $1,850 \mathrm{mt}$ will result in a neutral risk ( $50 \%$ ) that the 2011 adult biomass (ages $4+$ ) will be lower than the 2010 adult biomass (Figure 40). A catch of about $1,100 \mathrm{mt}$ will result in a neutral risk (50\%) that 2012 adult biomass will not increase by $10 \%$ from 2011.

## B. "split M 0.5" Model

Assuming a 2010 catch equal to the $1,350 \mathrm{mt}$ total quota, a combined Canada/USA catch of about 1,400 mt in 2011 will result in a neutral risk (50\%) that the fishing mortality rate in 2011 will exceed $F_{\text {ref }}$ whereas a catch of $1,350 \mathrm{mt}$ will result in a neutral risk (50\%) that the 2011 adult biomass (ages 4+) will be lower than the 2010 adult biomass (Figure 40). A catch of about 450 mt will result in a neutral risk (50\%) that 2012 adult biomass will not increase by $10 \%$ from 2011.

While management measures have resulted in decreased exploitation rates since 1995, adult biomass has fluctuated without any appreciable rebuilding. The continuing poor recruitment since the early 1990s is an important factor for this lower productivity. The 2003 year class made a substantial contribution to the fishery and population biomass, and it is projected to continue to be an important component in the population biomass and fishery catch biomass in 2010 (more than a quarter of the catch) and to a lesser extent in 2011 (between 13 and 18\% of the catch) (Figure 41-42, Table 24). With the passing of the 2003 year class through the population, rebuilding will not occur without improved recruitment and fishing at a level below $F_{\text {ref. }}$

## SPECIAL CONSIDERATIONS

Cod and haddock are often caught together in groundfish fisheries, although they are not necessarily caught in proportion to their relative abundance because their catchabilities to the fisheries differ. Due to the higher haddock quota, discarding of cod may be high and should be monitored. Modifications to fishing gear and practices, with enhanced monitoring, may mitigate these concerns.

Mechanisms that explain changes in either survey catchability or natural mortality could not be established. Changes in natural mortality could be aliasing 'missing' catch, particularly during the regulatory and reporting changes of the mid 1990s. It could also be aliasing emigration or imperfect designation of the boundaries for this component, though an excess of larger/older fish is not apparent in adjacent cod components.

There is no strong evidence to determine which of the two benchmark methods provides a better scientific basis for fishery management. The range of stock perceptions and outlooks from the two models reflect the substantial uncertainty in the assessment. Despite these uncertainties, all perceptions of historical and recent fishing mortalities are greater than $\mathrm{F}_{\text {ref }}$ (TRAC, 2010).

    Spawning protocol: 30% of maturity stages at 5 to 7.
```

## 2b. USA Management History

Closed Area I Haddock SAP
Access to small area of CAI to target haddock using longlines. Limited to $1,000 \mathrm{mt}$ haddock TAC. Season ends December 31.

## Eastern US/CA Area Haddock SAP Pilot Program

Access to northern corner of CAII and adjacent area to target haddock using separator trawl. Season: May 1 through December 31. Authorized use of Category B DAS.
Category B (regular) DAS Pilot Program
Vessels can use Category B (regular) DAS to target healthy stocks. Catch (kept and discarded) limited to 100 lbs. of cod, American plaice, white hake, witch flounder, ocean pout, SNE/MA winter flounder and windowpane flounder, 25 lbs.-DAS/250 lbs.-trip of yellowtail flounder. Maximum of 1,000 DAS can be used in each of four quarters from November 1, 2004 through October 31, 2005.
2005
January 14: Eastern US/CA reopened, yellowtail flounder daily poundage limit lifter (maximum remains 15,000 lbs./trip). Cod trip limit of 5,000 lbs./trip in Eastern US/CA area. Vessels fishing in Eastern US/CA area must use haddock separator trawl.
February 9: GB yellowtail flounder trip limit reduced to 5,000 lbs./trip in (entire) US/CA Management Area.
April 1: Eastern US/CA area closed until April 30, 2005, possession of GB yellowtail flounder prohibited in entire US/CA Management Area.
May 1: Eastern US/CA Area reopens at beginning of fishing year. Measures revert to those implemented May 1, 2004.

May 3: Haddock trip limit removed for remainder of the fishing year.
May 26: FW 40B implemented. Changes DAS leasing and transfer program, modifies GB Hook Sector provisions, adopts reporting requirements for herring vessels, modifies trip gillnet provisions.
CAII Yellowtail Flounder SAP
Changes starting date to July 1 , reduces trip limit to $10,000 \mathrm{lbs}$, number of trips per vessel per month is one, process established for adjusting the total number of trips.
June 8: Emergency action to control bycatch of haddock in the herring fishery establishes trip limit and overall TAC.
June 15: Implementation of FW 16 to the Sea Scallop FMP authorizes General Category Scallop vessel participation in scallop access areas. Scallop access areas in CAI and CAII open for all vessels on this date. June 27: Announcement that no trips will be allowed in the CAII Yellowtail Flounder SAP in FY 2005.
July 12: NE multispecies DAS vessels are limited to one trip per month in the Eastern US/CA area.
July 18: Multispecies DAS vessels are prohibited from fishing in the Category B (regular) DAS program in the GB cod stock area through July 31.
July 27: NE multispecies trawl vessels are required to use a haddock separator trawl when fishing in the Eastern US/CA area.
August 26: Eastern US/CA area is closed to all limited access multispecies DAS vessels because 90 percent of the GB cod TAC for the area is projected to be harvested.
September 6: CAI scallop access area is closed to General Category scallop vessels.
September 13:

## CAI Hook Gear Haddock SAP

FW 41 to the Northeast Multispecies FMP implemented. This action allows non-sector longline vessels to participate in the CAI Hook Gear Haddock SAP. The October 1 - December 31 season is divided in half, with sector vessels fishing in the first half and non-sector vessels in the second.
October 6: Participation in the Category B (regular) DAS Pilot Program is prohibited because the quarterly allocation of 1,000 DAS is used. The program ends for FY 2005.
October 31: Boundaries of the sea scallop access areas within CAI and the NLCA access areas are adjusted.
December 12: Northern shrimp fishery opens and will remain open through April 30, 2006.
December 21: The trip limit for NE multispecies vessels fishing for GB yellowtail flounder is changed from unlimited to 15,000 lbs per trip.
The quota for the second period of the CAI Hook Gear Haddock SAP is increased to 536.6 mt .
2006
January 12: The emergency rule allowing Atlantic herring vessels to possess haddock is extended for an additional 180 days.
January 31: Areas within groundfish closed areas that are open to scallop fishing through the scallop access area program close at midnight.

February 7: The trip limit for NE multispecies vessels fishing for GB yellowtail flounder is reduced to $1,500 \mathrm{lbs}$. per DAS up to a maximum of $15,000 \mathrm{lbs}$.
February 22: The trip limit for NE multispecies vessels fishing for GB yellowtail flounder is changed to 15,000 lbs. per trip regardless of trip length.
March 24: The trip limit for NE multispecies vessels fishing for GB yellowtail flounder is increased to an unlimited amount regardless of trip length.
April 30: Northern shrimp fishery season closes at midnight.
May 1: Implementation of an emergency rule to reduce fishing mortality on groundfish stocks while FW 42 is reviewed. Revised regulations are:

DAS: DAS charged at the differential rate of 1.4:1 for all areas outside the US/CA area.
Minimum Size: No changes for commercial vessels.
Gear: No changes.
Closures: No changes
Possession limits: GOM cod: $600 \mathrm{lbs}-\mathrm{DAS} / 4,000 \mathrm{lbs} .-t r i p . ~ G B ~ c o d: ~ 1,000 ~ l b s .-D A S / 10,000 ~ l b s .-t r i p ~$ outside of eastern US/CA area. CC/GOM yellowtail flounder: May, June October, November - 250 lbs. trip, other months 500 lbs .-DAS/2,000 lbs-trip. GB yellowtail flounder: $10,000 \mathrm{lbs}$. per trip; GB winter flounder: $5,000 \mathrm{lbs}$. per trip; SNE/MA yellowtail flounder: March -June, 250 lbs . trip, other months 750 lbs.-DAS/3,000 lbs-trip. White hake: 1,000 lbs.-DAS/10,000 lbs.-trip. Haddock: Trip limit removed for duration of emergency action.
Special Management Programs: Eastern US/Canada haddock SAP: Opening delayed until August 1. Category B (regular) DAS Program: Renewed, with vessels restricted to the US/CA Area, required to use a haddock separator trawl, limited to 500 days May-June, 1,000 days in other quarters, low trip limits on stocks of concern.
Recreational measures: Possession of GOM cod prohibited from November 1 - March 31. Minimum size for GOM cod increased to 24 in.
Other: Vessels allowed to fish inside and outside the eastern US/CA area on the same trip.
May 19: Announcement that CAII Yellowtail SAP will not open due to low TAC.
June 19: All trawl vessels fishing in the eastern US/CA area required to use a haddock separator trawl.
July 12: General category scallop vessel access to Nantucket Lightship Close area closed due to catching yellowtail flounder incidental catch TAC.
July 20: Limited access scallop vessel access to Nantucket Lightship Close area closed due to catching yellowtail flounder incidental catch TAC.
August 11: FW 43 implemented; addresses incidental catch of regulated multispecies by herring vessels. Haddock possession by midwater trawl vessels is allowed subject to a TAC.
September 6: Scallop vessel access to CAII closed due to yellowtail flounder bycatch.
October 1: CAI Hook Gear Haddock SAP opens.
November 22: Implementation of FW 42. Major regulatory changes:
DAS: DAS charged at the differential rate of 2:1 for an area in the inshore GOM (for an entire trip if any part of the trip fished in the area) and an area in SNE (only time fishing in the area).
Minimum Size: No changes for commercial vessels.
Gear: No changes.
Closures: No changes
Possession limits: GOM cod: 800 lbs-DAS/4,000 lbs.-trip. CC/GOM yellowtail flounder: 250 lbsDAS/1000 lbs. per trip. SNE/MA yellowtail flounder: 250 lbs-DAS/1000 lbs. per trip. Haddock trip limit unlimited. GB Yellowtail flounder: 10,000 lbs/trip. White Hake: 500 lbs-DAS/5,000 lbs-trip (this was an error - FW 42 says 1,000/10,000 per trip).
Special Management Programs: US/Canada Area: Opening delayed until August 1. Prohibition on discarding legal sized fish.
Category B (regular) DAS Program: Renewed for all areas. Trawl vessels required to use a haddock separator trawl, limited to 500 days May-June, 1,000 days in other quarters, low trip limits on stocks of concern. Prohibition on discarding legal sized fish.
Recreational measures: (same as emergency rule) Possession of GOM cod prohibited from November 1

- March 31. Minimum size for GOM cod increased to 24 in.

Other: (same as emergency rule) Vessels allowed to fish inside and outside the eastern US/CA area on the same trip.

December 1: Northern shrimp fishery opens: 151 days, seven days per week.
2007
March 5: Trawl vessels fishing in the eastern US/CA area allowed to use either a haddock separator trawl or a flounder net. GB yellowtail flounder trip limit reduced to $5,000 \mathrm{lbs}$.-trip for all vessels declaring into the eastern US/CA area.
April 5: Trip limit for GB yellowtail flounder increased to 25,000 lbs.-trip for the entire US/CA area for the remainder of the fishing year (through April 30).
April 25: Eastern U.S./Canada area closed to limited access multispecies vessels (through April 30, 2007).
April 30: Northern shrimp fishery closed at midnight.
May 1: Enforcement protocol for measuring nets changes. For mesh over 4.72 inches ( 120 mm ), weight used with net spade increased to 8 kg (from 5 kg ).
Eastern U.S./Canada area reopens.
No trips are authorized in the CAII yellowtail flounder SAP in 2007.
Trip limit for GB yellowtail flounder reduced to 3,000 pounds per trip in the U.S./Canada area.
Interim measures adopted for monkfish FMP restrict monkfish trip limits, reduce DAS that can be used in the SFMA, and does not allow carryover of monkfish DAS.
June 15: NLCA and CAI scallop access areas open.
June 20: Eastern US/CA area is closed to limited access multispecies DAS vessels due to cod catch.
July 8: The NLCA scallop access area is closed to General Category Scallop vessels.
July 15: The CAI scallop access area is closed to General Category Scallop vessels.
August 3: NMFS modifies permit renewal requirements for limited access multispecies vessels. Changes limit ability of vessels to fish in state waters outside of the FMP and retain eligibility for a federal limited access permit.
August 9: Minimum size for GB and GOM haddock caught by commercial vessels is reduced to 18 inches. Minimum size for all recreational vessels remains at 19 inches.
October 1: CAI Hook Gear Haddock SAP opens for GB Cod Hook Sector vessels.
October 20: The Eastern US/CA area is opened to limited access multispecies DAS vessels. The GB cod possession limit is $1,000 \mathrm{lb} /$ trip for all vessels declared into the Eastern US/CA Area or the Eastern US/CA Area SAP.
November 15: CAI Hook Gear Haddock SAP opens for non-sector vessels.
November 27: GB yellowtail flounder trip limit for vessels fishing in the US/CA management area increased to 7,500 lb/trip.
November 30: Eastern US/CA area closes
December 1: Northern Shrimp fishery opens. Season scheduled for 152 days, seven days per week.
December 11: CAI Hook Gear haddock SAP second period haddock quota increased to $4,789 \mathrm{mt}$.
2008
January 10: GB yellowtail flounder tip limit in the U.S/Canada management area set at 1,500 lbs./trip
January 24: Harvesting, possessing, and landing GB yellowtail flounder from the entire U.S./Canada management area is prohibited through April 30, 2008 (applies to trips that have not begun prior to announcement).
February 6: Minimum size for both GB and GOM haddock remains at 18 inches total length; extended through August 10, 2008.
March 12: Scallop elephant trunk access area closed to General Category scallop vessels.
April 30: Northern shrimp fishery closes.
May 1: GB yellowtail flounder trip limit set at 5,000 lbs./trip
Eastern U.S./Canada area opening delayed until August 1, 2008 for vessels fishing with trawl gear.
Eastern U.S./Canada area opened to longline gear but with a cod cap of 33.4 mt .
May 30: CAII yellowtail SAP remains closed (no trips authorized for FY 2008).
August 1: GOM and GB haddock minimum size reverts to 19 inches.
Eastern U.S./Canada management area opens to all vessels.
U.S./Canada Haddock SAP opens.

August 4: Happy Birthday, U.S. Coast Guard.
The Nantucket Lightship Closed Area closed to scallop vessels to prevent exceeding the yellowtail flounder incidental catch cap.
August 13: Haddock rope trawl (later called the Ruhle trawl, previously called the eliminator trawl) approved for use in the Category B (regular) DAS program and the U.S./Canada Haddock SAP.
September 15: Ruhle trawl authorized for use in the Eastern U.S./Canada management area.

```
October 1: CAI Hook Gear Haddock SAP opens for non-sector vessels.
October 23: GB yellowtail flounder trip limit reduced from 5,000 lbs./trip to 2,500 lbs./trip for vessels fishing in
the U.S./Canada management area.
November 15: CAI Hook Gear Haddock SAP opens for GB cod hook sector vessels.
December 1: Northern shrimp fishery opens for }180\mathrm{ days, seven days per week. Closure scheduled for May 29,
2009.
December 23: Landing limit for Eastern GB cod increased to 1,000 lbs./DAS up to a maximum of 10,000 lbs./trip
(applies to cod caught in the Eastern U.S./Canada management area).
December 30: Limited access General Category scallop fishery closed.
2009
January 26: NE Multispecies regulations adopted by FW 42 suspended as a result of a court order. No clear
explanation of what measures are affected.
February 13: NMFS identifies following measures as NOT impacted by the court order to suspend measures
adopted by FW 42:
- Recordkeeping and reporting requirements
- Gear restrictions
- DAS allocations
- Time and area closures
- Minimum fish sizes
- SAPs
- Recreational measures
- Cape Cod Hook Sector
- Some possession limits (GOM cod 800 lbs DAS-4,000 lbs/trip,, GB cod 1,000 lbs./DAS - 10,000 lbs./trip, US/CA area trip limits
Confusion continues on what regulations are not in effect.
February 17: Federal court rescinds decision to suspend FW 42 measures and limits suspension to differential DAS counting areas in the GOM and SNE/MA areas, and authorizes submission of DAS leasing requests through March 31, 2009 (vice normal March 1 deadline for such requests).
March 9: Eastern GB cod landing limit reduced to 500 lbs ./DAS - 5,000 lbs./trip. GB yellowtail flounder trip limit increased to \(5,000 \mathrm{lbs} /\) trip.
April 1: DELMARVA scallop access area closed to General Category scallop vessels.
April 16: Eastern US/CA area closed until May 1.
May 1: Interim rules in effect to reduce overfishing on multispecies stocks until Amendment 16 implemented.
Major changes:
DAS: DAS allocations reduced according to Amendment 13 schedule. Category A DAS are reduced to 45 percent of the permit's DAS baseline, an 18 percent reduction from the previous year['s allocations. Differential DAS area increased in SNE/MA.
Minimum Size: Haddock 18 inch minimum size.
Gear: No changes.
Closures: No changes
Possession limits: GOM cod: 800 lbs-DAS/4,000 lbs.-trip. GB cod: 1,000 lbs./DAS-10,000 lbs./trip (eastern US/CA area \(500 \mathrm{lbs} . / \mathrm{DAS}-5,000 \mathrm{lbs} . / t r i p) . ~ C C / G O M ~ y e l l o w t a i l ~ f l o u n d e r: ~ 250 ~ l b s-D A S / 1000 ~\) lbs. per trip. SNE/MA yellowtail flounder: 250 lbs-DAS/1000 lbs. per trip. Haddock trip limit unlimited. GB Yellowtail flounder: 5,000 lbs/trip. White Hake: 1000 lbs-DAS/10,000 per trip). GB winter flounder: 5,000 lbs./trip. Witch flounder: 1,000 lbs./DAS-5,000 lbs./trip. Possession of ocean pout, northern windowpane flounder, and SNE/MA winter flounder prohibited.
Special Management Programs: US/Canada Area: Opening delayed until August 1 for trawl vessels.
Prohibition on discarding legal sized fish. SNE/MA winter flounder SAP suspended. State waters winter flounder exemption eliminated. CAI Hook Gear Haddock SAP expanded to January 31, area increased, no separation between common pool and sector participants.
Recreational Measures: GB cod bag limit of n10 cod per person per day for party/charter vessels; retention of GOM cod prohibited from November through April 15; retention of SNE/MA winter flounder prohibited; haddock minimum size reduced to 18 inches. Other: Conservation tax removed from DAS transfers.
```

May 6: Limited access general category scallop fishery closed to IFQ vessels until June 1.

May 29: Northern shrimp fishery closes.
June 5: GB yellowtail flounder trip limit reduced to 2,500 lbs./trip
June 26: eastern US/CA Area closed to all vessels until August 1 (including fixed gear vessels) to prevent exceeding first quarter GB cod TAC.
June 29: CAII Scallop Access Area closed to prevent exceeding GB yellowtail flounder cap.
July 6: GB winter flounder trip limit removed. White hake trip limit increased to 2,000 lbs./DAS-10,000 lbs./trip.
July 19: Limited access general category scallop fishery closed to IFQ vessels until September 1.
September 15: Limited access general category scallop fishery closed to IFQ vessels until December 1.
September 17: Use of flounder trawl net prohibited when fishing in the Eastern US/CA area.
November 2: Mid-water trawl vessels fishing in CAI subject to 100 percent observer coverage, prohibition on releasing catch before sampling by observer.
November 20: In the US/CA management area, trawl vessels required to use a haddock separator trawl or Ruhle trawl south of 41-40N latitude. Any vessel fishing in this area and other areas cannot use any other gear on the same trip. Vessels fishing north of 41-40N for the entire trip can use any legal gear.
December 1: Northern shrimp fishery opens for 180 days; scheduled to close May 29, 2010.

Table 3. Nominal landings (mt) of cod from eastern Georges Bank by gear and month for Canada, 19992009.

| Year | Gear | Jan | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 4. Length and age samples from the USA and Canadian fisheries on eastern Georges Bank. For Canadian fisheries, at-sea observer samples are included since 1990. The first quarter age samples are supplemented with USA fishery age samples from 5Zjm for 1978 to 1986 and DFO survey age samples for 1987-2009; the numbers are shown in brackets.

| Year | USA |  | Canada |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Lengths | Ages | Lengths | Ages |
| 1978 | 2,294 ${ }^{1}$ | 384 | 7,684 | 1,364 |

Figure 3. Canadian and USA landings and discards of cod from eastern Georges Bank, 1978 to 2009.

Figure 4. Proportion of Canadian gear specific landings of cod from eastern Georges Bank, 1978 to 2009.

Figure 5. Proportion of Canadian and USA quarterly landings of cod from eastern Georges Bank, 1978 to 2009.

Figure 6. Landings (wide bars) and sampling (narrow dark bars) of cod by gear and month from the 2009 Canadian groundfish fishery on eastern Georges Bank.

Figure 7. Comparison of cod length composition from port and at sea observer sampling of the 2009 Canadian bottom trawl (OTB), longline (LL) and gillnet (GN) fisheries on eastern Georges Bank.

Figure 8. Cod catches at length by gear from the 2009 Canadian fisheries on eastern Georges Bank.

Figure 9. Cod landings and discards at length from the 2009 Canadian fisheries on eastern Georges Bank.

Figure 10. Cod landings and discards at length from the 2009 USA fisheries on eastern Georges Bank.

Figure 11. Catch composition from the 2009 Canadian and USA fisheries on eastern Georges Bank.

Figure 12. Catch at age in numbers (right) and weight (left) for landings and discards of cod from the 2009 eastern Georges Bank fisheries.

Figure 13. Total catch at age (numbers) of cod (left) and proportion of catch at age (right) from eastern Georges Bank for 1978 to 2009. The bubble area is proportional to the magnitude. The light green circles are the 2003 year class and the light blue circles are the 2006 year class.

Figure 14. Average weights at ages 2 to 8 of cod from the eastern Georges Bank fishery, 1978 to 2009.

Figure 15. Stratification used for the NMFS surveys. The eastern Georges Bank management unit is indicated by shading.

Figure 16. Stratification used for the DFO survey. The eastern Georges Bank management unit is indicated by shading.

Figure 17. Spatial distribution of ages 3+ cod on eastern Georges Bank from the DFO survey for 2010 (right panel) compared to the average for 2000 to 2009 (left panel).

Figure 18. Spatial distribution of ages $3+$ cod on eastern Georges Bank from the NMFS spring survey for 2009 (right panel) compared to the average for 1999-2008 (left panel).

Figure 19. Spatial distribution of ages $3+$ cod on eastern Georges Bank from the NMFS spring survey for 2010 (right panel) compared to the average for 2000-2009 (left panel).

Figure 20. Spatial distribution of ages 3+ cod on eastern Georges Bank from the NMFS autumn survey for 2009 (right panel) compared to the average for 1999-2008 (left panel).

Figure 21. Survey abundance at age (numbers) of eastern Georges Bank cod. The bubble area is proportional to magnitude within each survey. Conversion factors to account for changes in door type, net and survey vessel were applied to the NMFS surveys. The NMFS spring survey was conducted using a modified Yankee 41 during 1978 to 1981 (lighter bubbles). The 2003 year class is identified with lighter green bubbles whilst the 2006 year class is identified with lighter blue bubbles.

Figure 22. Survey biomass index and smoothed trend (black line) for different age group of eastern Georges Bank cod.

Figure 23. Beginning of year weight at age of eastern Georges Bank cod from DFO and NMFS spring survey.

Figure 24. Condition, measured as average weight at three representative length groupings for eastern Georges Bank cod from the DFO survey.

Figure 25. Survey catchability (q) for the DFO, NMFS spring and NMFS fall surveys from the "split M 0.2 " (left) and "split M 0.5 " (right) model formulations.

Figure 26. Assessment biomass trends comparison with DFO, NMFS spring and NMFS fall surveys for "split M 0.2 " (left) and "split M 0.5 " (right) model formulations.

Figure 27. Residuals by year and age group from survey indices for eastern Georges Bank cod. Solid bubbles indicate positive values, open bubbles indicate negative values and bubble area is proportional to magnitude. The NMFS spring survey was conducted using a modified Yankee 41 during 1978 to 1981 (pale blue bubbles). The upper figures are from the "split M 0.2 " model, the lower figures are from the "split M 0.5 " model.

Figure 28. Retrospective pattern for recruitment at age 1, 3+ biomass and fishing mortality of eastern Georges Bank cod.

## Appendix (From TRAC Res Doc. 2009/01)

## Discards of Cod from the 2008 Canadian Groundfish Fishery on Eastern Georges Bank

## Data and Methods

Discards of cod from the Canadian groundfish fishery were estimated using the ratio of sums estimator methods described by Gavaris et al (2007b). Landings of cod and haddock for 2008 were obtained from the fisheries statistics database maintained by the Maritimes Region of Fisheries and Oceans Canada. Trips were classified as observed or unobserved. Following Gavaris et al (2007b), the basic record unit was the aggregate of catches from a trip within each zone, referred to as a sub-trip. Use of a separator panel when fishing with a bottom otter trawl on Georges Bank was mandatory in 2008, regardless of whether there was an observer on board. Therefore no sub-trips were excluded due to removal of the separator panel. Trips where the observer deployment was for management purposes, rather than routine monitoring, were excluded as these might not be representative.

As in previous recent years (Van Eeckhaute and Gavaris 2004, Gavaris et al 2007b), virtually all the cod for 2008 were caught in Zones A and B during fishing targeting for haddock (Table A1, Figure A1). Accordingly, discards were only derived for Zones A and B and for the designated fleets targeting haddock, i.e. excluding pollock and yellowtail flounder targeted fishing by mobile gear and cod targeted fishing by gillnet and handline. Sub-trips that sought pollock were identified as those where the catch of pollock exceeded the catch of cod and haddock or observed sub-trips where the declared species sought was pollock. A small amount of catch by a vessel experimenting with a new bottom trawl configuration was excluded from comparisons because the bycatch from this vessel might not be comparable to the rest of the fleet. The amount of cod landed from other zones by all the excluded fishing activity was relatively low; therefore any potential estimated discards would be inconsequential.

The calculation of discards uses a landings multiplier that is based on ratios of cod to haddock. Factors that are expected to affect the species composition include fishing fleet, fishing ground location and season. Quarters were used to stratify season.

The Canadian quotas are sub-allocated to quota groups. Sub-allocation of shares to quota groups varies by species. Therefore, the quota mix varies substantially by quota group. The quota mix can be an important determining factor in discarding behaviour. Accordingly, fishing fleets were defined by quota groups (Table A2). Generally, quota groups comprise vessels that are similar with respect to size and gear. A quota group's allocation may be fished by vessels smaller than those in the group under the Temporary Vessel Replacement Program (TVRP is a mechanism by which a fleet can contract another fleet to catch their quota without transferring the quota). Almost all of the 2008 catch by the MG 65'-100' and the >100' fleets was taken by vessels less than 65' under the TVRP program.

Zones were defined for Georges Bank based on areas of fishing concentration and homogeneity of species composition (Figure A1). While there appears to be considerable local scale variation in species composition, the zones could not be made smaller given the observer sampling intensity.

The data for each fishing fleet, zone and quarter grouping were analyzed separately to derive an estimator of the landings multiplier that was used to compute discards.

## Results and Discussion

The ratio of sums method was applied to obtain the landings multipliers by fishing fleet, zone and quarter (Table A3). The associated standard errors from the bootstrap analyses are also shown. Bootstrap confidence distributions of the landings multiplier were examined to determine if it could be inferred that discarding occurred. The percentile and bias corrected confidence distributions were generally coincident, indicating that the bias is small. Discards were calculated for cases where the reference landings multiplier of 1 intersected the bias corrected confidence distribution at a probability of 0.2 or less. Discarding was only inferred for FG<45 in quarter 3, zone $B$ (Figure $A 2$ ) and $M G<65$ in quarter 1, zone $B$ (Figure A3). There was insufficient data to estimate landings multipliers for FG 45-65, FG 65-100 and MG 65-100. Although discarding might be inferred for $M G>100$ in quarter 1, zone $B$, the estimated discards were less than 0.5 mt and therefore not used (Figure A4). Discarding might also be inferred for FN in quarter 1, zone B, but was only marginally significant with low sampling, and therefore also not used (Figure A5). In total, discards of cod from the Canadian groundfish fisheries on Georges Bank in 2008 were 103 mt (Table A4).

Table A1. Landings of cod used in the analysis of cod discards from the Canadian fisheries on Georges Bank in 2008. Trips targeting pollock, yellowtail and cod were removed. Discards may occur during unobserved fishing. Discard calculations were examined for haddock targeted fishing in Zones $A$ and $B$ by quarter for the designated fleets (shaded cells).
