#### Abstract

Combined Canada/USA catches averaged 17,208 mt between 1978 and 1993, declined to $1,683 \mathrm{mt}$ in 1995, then fluctuated around $3,000 \mathrm{mt}$ until 2004 and subsequently declined again. Catches in 2010 were 1,326 mt, including 221 mt of discards. Canadian and USA catches were 840 mt and 486 mt in 2010, respectively.

Two alternative VPA model formulations, "split M 0.2 " and "split M 0.5 ", were used in the assessment.

Adult population biomass (ages 3+) declined from about 50,000 mt in 1990 to below 10,000 mt in 1995. Since 1995, adult population biomass from the "split M 0.2 " model has fluctuated between $3,100 \mathrm{mt}$ and $10,100 \mathrm{mt}$; from the "split M 0.5 " model it has fluctuated between $4,200 \mathrm{mt}$ and $12,600 \mathrm{mt}$. Biomass at the beginning of 2011 was $3,288 \mathrm{mt}$ from the "split M 0.2 " model and $5,088 \mathrm{mt}$ from the "split M 0.5 " model, the second lowest in the time series from both models.

The 2003 year class was the highest recruitment observed since 2000, but was less than half of the average (about 10 million) during 1978-1990, when productivity was considered to be higher. The 2002 and 2004 year classes were the two lowest on record. Initial indications were that the 2007, 2008, and 2009 year classes were less than 2 million. Recruitment indices from the bottom trawl surveys for the 2010 year class were higher than those for recent year classes.

Fishing mortality ( $\mathrm{F}_{4-9}$ ) was high prior to 1994. F declined in 1995 to 0.36 for the "split M 0.2 " model and to 0.24 for the "split M 0.5 " model due to restrictive management measures. $F$ in 2010 was estimated to be 0.41 from the "split M 0.2 " model and 0.25 from the "split M 0.5 " model. F has been consistently above $\mathrm{F}_{\text {ref }}=0.18$ for both model formulations since the beginning of the time series (1978).

Assuming a 2011 catch equal to the $1,050 \mathrm{mt}$ total quota, a combined 2012 Canada/USA catch of about 600 mt ("split M 0.2 " model) and 925 mt ("split M 0.5 " model) will result in a neutral risk ( $50 \%$ ) that the fishing mortality rate in 2012 will exceed $F_{\text {ref. }}$. A catch of $1,350 \mathrm{mt}$ ("split M 0.2 " model) and 900 mt ("split M 0.5 " model) will result in a neutral risk (50\%) that the 2013 adult biomass (ages 4+) will be lower than 2012. A catch of about 1,000 mt ("split M $0.2^{\prime \prime}$ model) and 300 mt ("split M 0.5" model) will result in a neutral risk (50\%) that 2013 adult biomass will not increase by $10 \%$ from 2012. A catch of 650 mt will result in a neutral risk (50\%) that 2013 adult biomass will not increase by $20 \%$ from the "split M 0.2 " model, but even with no catch, there is more than a $50 \%$ probability that biomass will not increase by $20 \%$ from the "split M 0.5 " model.

## RÉSUMÉ

Les captures combinées du Canada et des États-Unis, qui étaient en moyenne d'environ 17208 tm entre 1978 et 1993, sont tombées à 1683 tm en 1995, puis ont fluctué alentour de 3000 tm jusqu'en 2004, avant de décliner à nouveau. Les captures totales de 2010 se chiffraient à 1326 tm , dont 211 tm de rejets, soit 840 tm pour le Canada et 486 tm pour les États-Unis

Deux formes d'APV ont été utilisées dans l'évaluation : un « modèle fractionné $M=0,2$ » et un « modèle fractionné $\mathrm{M}=0,5$ ».

La biomasse de la population adulte (âges 3 +) a diminué, passant d'environ 50000 tm en 1990 à moins de 10000 tm en 1995. Depuis 1995, la biomasse de la population adulte a fluctué entre 3100 tm et 10100 tm selon le «modèle fractionné $M=0,2$ » et entre 4200 tm et 12600 tm selon le «modèle fractionné $M=0,5$ ». Elle se chiffrait au début de 2011 à 3288 tm selon le « modèle fractionné $\mathrm{M}=0,2$ » et à 5088 tm selon le selon le « modèle fractionné $\mathrm{M}=0,5$ », ce qui la situait à l'avant-dernier rang de ses valeurs les plus basses selon les deux modèles.

La classe d'âge 2003 a représenté le plus fort recrutement observé depuis 2000, mais elle n'atteignait pas la moitié de la moyenne (environ 10 millions de poissons) de 1978-1990, période où la productivité était considérée comme plus élevée. Les classes d'âge 2002 et 2004 étaient les plus faibles observées à ce jour. D'après les indications initiales, l'effectif des classes d'âge 2007, 2008 et 2009 était inférieur à 2 millions de poissons. Pour ce qui est de la classe d'âge 2010, les indices de recrutement provenant des relevés au chalut de fond étaient supérieurs à ceux des récentes classes d'âge.

La mortalité par pêche ( $\mathrm{F}_{4-9}$ ) était élevée avant 1994. F a diminué en 1995 à 0,36 selon le « modèle fractionné $M=0,2$ » et à 0,24 selon le « modèle fractionné $M=0,5$ », en raison de mesures de gestion strictes. En 2010, F a été estimée à 0,41 d'après le «modèle $\mathrm{M}=0,2$ » et à 0,25 d'après le «modèle fractionné $M=0,5 »$. $F$ a été constamment supérieure à $F_{\text {rét. }}=0,18$, selon les deux modèles, depuis le début de la série chronologique (1978).

Si les captures sont égales au quota total de 1050 tm en 2011, des captures combinées du Canada et des États-Unis qui seraient en 2012 de 600 tm (« modèle fractionné $\mathrm{M}=0,2 »$ ) et de 925 tm (« modèle fractionné $M=0,5 »$ ) se traduiraient par un risque neutre ( $50 \%$ ) que le taux de mortalité par pêche dépasse $F_{\text {rét. cette année-là. Des captures de } 1350 \mathrm{tm} \text { (« modèle }}$ fractionné $\mathrm{M}=0,2$ ») et de 900 tm (« modèle fractionné $\mathrm{M}=0,5 »$ ) se solderaient par un risque neutre ( $50 \%$ ) que la biomasse des adultes (âges $4+$ ) en 2013 soit inférieure à celle de 2012. Des captures d'environ 1000 tm (《 modèle fractionné $\mathrm{M}=0,2$ ») et 300 tm (《 modèle fractionné $\mathrm{M}=0,5 »$ ) se traduiraient par un risque neutre ( $50 \%$ ) que la biomasse des adultes en 2013 n'augmente pas de $10 \%$ par rapport à 2012. Des captures de 650 tm correspondraient à un risque neutre ( $50 \%$ ) que la biomasse des adultes en 2013 n'augmente pas de $20 \%$, selon le «modèle fractionné $M=0,2$ », mais même en l'absence de captures, il y a plus de $50 \%$ de probabilité que la biomasse des poissons n’augmente pas de $20 \%$, selon le «modèle fractionné $\mathrm{M}=0,5$ ».

## INTRODUCTION

The basis and background for the delineation of management units of cod on Georges Bank and the vicinity were reviewed and summarized at the 2009 Eastern Georges Bank cod benchmark assessment meeting (O'Brien and Worcester, 2009). For the purpose of a sharing agreement and consistent management by Canada and the USA, agreement was reached that the transboundary management unit for Atlantic cod would be limited to the eastern portion of Georges Bank (DFO Statistical Unit Areas 5Zej and 5Zem; USA Statistical Areas 551, 552, 561 and 562)) (DFO, 2002). The management area is shown in Figure 1. The USA has a requirement for management advice for the Georges Bank cod stock ( $5 Z+$ SubArea 6). The status quo has been to use an assessment of cod in 5Zjm for transboundary management advice and an assessment of cod in 5Z+6 for USA domestic management advice. While other options could be followed, this option is less disruptive to the existing processes. This approach requires concurrent assessment reviews of 5Zjm and of 5Z+6 to harmonize results.

The model formulation established by the 2002 Eastern Georges Bank cod benchmark assessment (O'Boyle and Overholtz, 2002) was used for the eastern Georges Bank cod assessment from 2002 to 2008. In recent assessments the results exhibited a domed catchability pattern by age in both the DFO and NMFS spring surveys, and the descending limb of the fishery partial recruitment became increasingly steep for older ages. The resulting assessment generated appreciable 'cryptic' biomass that could not be observed by either the fishery or the surveys. An examination of the implications of eliminating the first quarter fishery indicated that the magnitude of those removals was not large enough to appreciably alter the annual size composition. Therefore, a marked change in fishery partial recruitment after the mid 1990s, a key feature of the 2002 benchmark model formulation, was not supported. An Eastern Georges Bank cod benchmark assessment was conducted in 2009 to address these concerns and the details of the model formulations that were agreed upon were documented in Wang et al. (2009a).

The current assessment applied the 2009 benchmark formulations using Canadian and USA fishery information updated to 2010 including commercial landings and discards, the Fisheries and Oceans Canada (DFO) survey updated to 2011, the National Marine Fisheries Services (NMFS) spring survey updated to 2011 and the NMFS fall survey updated to 2010.

## FISHERY

## Commercial Fishery Catches

Historical catch data were updated at the 2009 benchmark meeting (Wang et al., 2009a). For the 2010 assessment, the USA landings for 2007-2009 were re-estimated due to auditing of the commercial landings database that included changes in area designation of landings. The effect on the total eastern Georges Bank cod landings was minimal: a 9\% increase in 2007, a 3\% decrease in 2008 and less than a 1\% increase in 2009. Combined Canada/USA catches averaged $17,208 \mathrm{mt}$ between 1978 and 1993, peaking at $26,464 \mathrm{mt}$ in 1982, and then declined to $1,683 \mathrm{mt}$ in 1995. They fluctuated around $3,000 \mathrm{mt}$ until 2004 and subsequently declined again. Catches in 2010 were 1,326 mt, including 221 mt of discards (Table 1, Figure 2). Catches include USA and Canadian discards in all years where discard estimates were available.

Canadian catches peaked at $17,898 \mathrm{mt}$ in 1982 and declined to $1,140 \mathrm{mt}$ in 1995 (Table 1, Figure 3). Since 1995, with lower cod quotas, the fishery has reduced targeting for cod through changes in fishing practices, including the introduction of the cod separator panel for bottom
trawls in 1999 (Table 2). From 1995-2009, Canadian catches fluctuated between 859 mt and $3,405 \mathrm{mt}$ (Table 1). In 2010, total catch including discards were 840 mt against a quota of $1,012 \mathrm{mt}$, taken primarily between June and December by otter trawl and longline (Table 3, Figure 4 and 5). All 2010 landings were subject to dockside monitoring and at sea observers monitored close to $18 \%$ by weight of the mobile gear fleet landings ( $16 \%$ of trips), $6 \%$ by weight of the fixed gear landings ( $8 \%$ of trips) and $10 \%$ of the gillnet fleet landings ( $11 \%$ of trips).

Canadian regulations prohibit the discarding of undersized fish from the groundfish fishery. The ratio of sums method, which uses the difference in ratio of cod to haddock from observed and unobserved trips, was applied to estimate discards of cod. Discards from the Canadian groundfish fishery were estimated for 1997 to 1999 (Van Eeckhaute and Gavaris, 2004) and for 2005 and 2006 (Gavaris et al., 2006, 2007b) (Table 1). In 2007, no discards were attributed to the mobile gear fleet because of the high observer coverage (99\%) and discards for the fixed gear fleet could not be calculated because of the low observer coverage but were assumed to be negligible as discards had not been detected in previous years (Clark et al., 2008). Discards were calculated for both fleets in the 2009 and 2010 assessments (Wang et al., 2009b, Clark et al., 2010). Cod discards from the 2010 Canadian groundfish fishery were estimated at 48 mt from the mobile gear fleet (Table 1, Appendix A).

Since 1996, the Canadian scallop fishery has not been permitted to land cod. Landings until 1995 included those landings reported by the scallop fishery. Estimated discards of cod by the Canadian scallop fishery ranged up to 200 mt annually since 1978 (Van Eeckhaute et al., 2005). The 3-month moving average observed discards rate has been applied to scallop effort to estimate discards from scallop fishery since 2005 (Gavaris et al., 2007a). In 2010, estimated discards of cod by the Canadian scallop fishery were 44 mt (Van Eeckhuate et al., 2011, Table 1).

USA catches increased from $5,502 \mathrm{mt}$ in 1978 to $10,550 \mathrm{mt}$ in 1984, then declined and fluctuated around 6,000 mt between 1985 and 1993 (Table 1, Figure 3). Since December 1994, a year-round closure of Area II (Figure 1) has been in effect, with the exception of a Special Access Program in 2004 and 2010. Minimum mesh size limits were increased in 1994, 1999 and in 2002. Quotas were introduced in May 2004. Limits on sea days, as well as trip limits, have also been implemented (Table 2). With the implementation of a catch share system in 2010, most of the fleets are now managed by quotas. USA catches during 1994-2000 ranged between 544 mt and $1,207 \mathrm{mt}$ and increased to $1,955 \mathrm{mt}$ in 2003. In 2009, USA landings increased to 433 mt , the highest landings since 2004. Landings then declined to 357 mt in 2010. The majority of USA landings are usually taken in the second calendar quarter with the least amount landed during the third quarter (Figure 5). Otter trawl accounted for 76\% and longline gear about 23\% of the landings, with the remainder taken by gillnet and other unknown gears during 2010. Total USA catch (landings and discards combined) was 486 mt for calendar year 2010.

Discards by USA groundfish fleets occur because of trip limits and minimum size restrictions. In September 2008, the 'Ruhle trawl', which reduces by-catch of cod, was authorized for use on eastern Georges Bank. Cod discarded in the eastern Georges Bank area by otter trawl and scallop fisheries were estimated using the NEFSC observer data from 1989-2010. A ratio of discarded cod to total kept weight of all species (d:k) was estimated on a trip basis. Total discards (mt) were estimated from the product of $\mathrm{d}: \mathrm{k}$ and total commercial landings. The estimated discards of cod in the groundfish fishery were 129 mt in 2010, a decrease from 194 mt discarded in 2009 (Table 1, Figure 3). Otter trawl gear accounted for almost all of the 2010 discarded fish ( 128.8 mt ) with scallop gear accounting for the remainder. Observers noted that the majority of fish (60\%) were discarded because of minimum size restrictions, culling for a
better price when a trip quota was in effect (20\%) and because there was no market for small fish (11\%).

## Size and Age Composition

The size and age compositions of the 2010 landings by the Canadian groundfish fishery were derived from port and at-sea samples from all principal gears and seasons (Table 4, Figure 6). There were representative samples from the mobile gear fishery over all the fishing months. For the fixed gear fleet, except in the second quarter when landings were low, the samples spread representatively over the fishing months. Comparison of port and at-sea length frequencies did not indicate any discrepancies for otter trawlers. Fixed gear observer samples tended to have more small fish than the port samples, especially in September, indicating that discarding might have occurred (Figure 7). However, discarding could not be inferred using the ratio of sums method, perhaps because of the low observer coverage. At-sea samples were pooled with port samples to derive catch at length and age. Landings peaked at $58 \mathrm{~cm}(23 \mathrm{in})$ for bottom trawlers and 58 to 64 cm ( 23 to 25 in ) for longliners. Gillnetters caught fewer cod but these fish were larger, peaking at 70 cm (28 in) (Figure 8). The gear-combined landings peaked at 58 cm (23 in) (Figure 9).The size composition of cod discards from the 2010 Canadian scallop fishery was derived from at-sea sampling. Cod discards from the scallop fishery peaked at 55 cm ( 22 in ) (Figure 8). The discards from otter trawlers were assumed to have the same size composition as the landings from the otter trawl fishery. The Canadian combined cod discards in 2010 from otter trawl and scallop fishery peaked at 58 cm (23 in) (Figure 9).

The size and age compositions of the 2010 USA fishery landings on eastern Georges Bank were estimated using port samples of length frequencies and age structures collected from all principal gears and seasons by market category (Table 4). The size frequencies and age composition of discarded fish were estimated using at-sea observer samples of length frequency and commercial and NEFSC survey age-length keys from the same area and season. Landings in 2010 peaked at 65 cm ( 25.6 in ) and discards peaked at 53 cm (21 in) (Figure 10).

The catch composition, combined landings and discards for Canada and the USA, is shown in Figure 11. Canadian and USA catches peaked at similar lengths (Canada: 58 cm ( 22 in ); USA: $56-65 \mathrm{~cm}$ (22 to 26 in )), but USA catches contained proportionally more small fish than Canadian catches.

Otoliths taken from port and at-sea observer samples were used for age determinations. Comparisons have indicated good agreement between DFO and NMFS age readers (Table 5).

Canadian catch-at-age composition was obtained by applying quarterly fishery age-length keys to the size composition. The age-length key from the 2010 DFO survey was used to augment the first quarter key.

The age composition of the re-estimated 2007-2009 and the 2010 USA landings was estimated by market category by applying age-length keys to the size composition pooled by calendar quarter, semi-annually, or annually depending on the number of available length samples. Based on the USA sampling protocol, 1 sample per 100 mt of landings (i.e. where 1 length sample=100 fish and 1 age sample=20-25 fish), the age sampling of eastern Georges Bank cod landings was sufficient during 2007-2010 so there was no need to supplement the NEFSC age data with DFO age data as had been done in previous years. Discards at age from the USA groundfish and scallop fisheries (1989-2010), the Canadian groundfish fishery (1997-2010) and the Canadian scallop fishery (1978-2010) were included in the assessment.

The combined Canada/USA 2010 fishery age composition by number was dominated by the 2006 year class at age 4 (44\%), followed by the 2007 year class at age 3 (23\%) and the 2005 year class at age 5 (15\%) (Table 6, Figure 12). The 2003 year class at age 7 continued to make some contribution to the 2010 catch (7\%). By weight, the 2006 year class still dominated the 2010 fishery (41\%) followed by the 2005 (19\%) and 2007 year classes (17\%) (Figure 12). The contribution to the catch of ages 7 and older continued to be small in recent years (Table 6, Figure 12), $8 \%$ by number ( $1 \%$ from $8+$ ) and $17 \%$ by weight in 2010, even with the inclusion of age 7 fish from the stronger 2003 year class (Table 6, Figure 12 and 13).

Fishery weights at age showed a declining trend starting in the early 1990s (Table 7, Figure 14). In 2010, the weight at age decreased for all ages except for age 3 from 2009.

## ABUNDANCE INDICES

## Research Surveys

Surveys of Georges Bank have been conducted by DFO each year (February/March) since 1986 and by NMFS each fall (October) since 1963 and each spring (April) since 1968. All surveys use a stratified random design (Figures 15 and 16). Most of the DFO surveys have been conducted by the CCGS Alfred Needler. A sister ship, the CCGS Wilfred Templeman, conducted the survey in 1993, 2004, 2007 and 2008, and another vessel, the CCGS Teleost, conducted 6 of the sets in 2006. No conversion factors were applied. For the NMFS surveys, two vessels have been employed and there was a change in the trawl door in 1985. Vessel and door type conversion factors derived experimentally from comparative fishing (Table 8) have been applied to the survey results to make the series consistent (Forrester et al. 1997). Additionally, two different trawl nets have been used on the NMFS spring survey, a modified Yankee 41 from 1973-81 and a Yankee 36 in other years, but no net conversion factors were available for cod. A new net and vessel (FSV Henry B. Bigelow), with revised station protocols have been used to conduct the NMFS spring and fall surveys since 2009. Calibration factors by length were calculated for Atlantic cod for the data collected by the FSV Henry B Bigelow to make the data equivalent to previous surveys conducted by $F R V$ Albatross IV. The new research vessel/net combination tended to catch more cod at all lengths, but also proportionally more small cod. The calibration factors at length applied to the 2009, 2010 and 2011 NMFS spring survey and 2009 and 2010 NMFS fall survey are shown in Table 9 (Brooks et al. 2010).

The spatial distribution of ages 3 and older cod caught during the 2011 DFO survey was similar to those observed from surveys over the previous decade, with most fish concentrated on the northeastern part of Georges Bank (Figure 17). Total catch in numbers in the 2011 DFO survey was low, less than half of the 2010 survey (Table 10). The 2003 year class at age 8 accounted for $3 \%$ by number from this survey. The 2006 year class was still prominent in the 2011 survey ( $33 \%$ by number), consistent with the previous years' survey results ( $30 \%$ and $43 \%$ by number in 2009 and 2010, respectively). The 2007 year class at age 4 looked moderate from this survey ( $24 \%$ by number). Initial indication of the 2010 year class at age 1 was promising in the 2011 DFO survey ( $5 \%$ by number), the strongest since the 2003 year class (Table 10, Figure 20).

With the calculation of the calibration factors for cod (Table 9), the 2011 NMFS spring survey distribution of age $3+$ cod showed a similar distribution pattern relative to the previous decade (Figure 18). The 2011 spring survey total catch in numbers, however, was the second lowest in the time series (Table 11). The 2003 year class at age 8 was only $3 \%$ by number from this survey. The 2006 year class did not appear particularly strong in the 2011 NMFS spring survey
(16\% by number) although it was dominant in the 2009 and 2010 NMFS spring survey (41\% and $43 \%$ by number). The 2007 year class at age 4 was moderate ( $29 \%$ by number) and the 2010 year class at age 1 accounted for $10 \%$ by number in the 2011 survey (Table 11, Figure 20).

The distribution of age 3+ cod from the 2010 NMFS fall survey was similar to the average distribution in the last decade of surveys (Table 12, Figure 19). There was a large tow on the northeastern part of Georges Bank, in which the 2010 year class at age 0 was dominant ( 41 age 0 fish out of a total of 52 fish caught in the tow). Compared to the 2009 survey, the total catch in numbers of ages 1+ was low in 2010. The 2006 year class at age 4 accounted for the largest catch by number at 38\% (Table 12, Figure 20).

With the exception of the 2003 and 2006 year classes and potentially 2010 year class, the survey abundance at age (Tables 10-12, Figure 20) shows poor recruitment since the 1990 year class in all 3 surveys. The 2003 year class appears strong in the spring surveys until age 7 and in the fall surveys until age 3. The 2006 year class appears prominent in the surveys, but not as strong as the 2003 year class. Initial indications for the 2010 year class are promising from the 2011 DFO and 2010 NMFS fall surveys. Compared with pre-1990 surveys, representation at older ages and younger ages in recent years continues to be poor (Figure 20).

Biomass indices at age were calculated by applying weight at age to the abundance indices at age. The survey biomasses in 2011 for all 3 surveys are lower than 2010, and the NMFS spring survey is the second lowest in the time series (Figure 21). Survey biomass indices have been lower since the mid-1990s, and continue to decline for all ages (Figure 22).

The average weights at age derived from the DFO survey and NMFS spring survey were used to represent the population weight at age for the beginning of the year. All weights at age display a declining trend since the early 1990s (Table 13, Figure 23). Except for age 6, the weights at age for all other ages in 2011 were lower than 2010 surveys. Fulton's K, an indicator which uses weight-length relationship to measure fish condition, was calculated from the DFO survey data. It showed notable downward trends for all the ages in recent years (Figure 24).

## HARVEST STRATEGY

The Transboundary Management Guidance Committee (TMGC) has adopted a strategy to maintain a low to neutral risk of exceeding the fishing mortality limit reference, $\mathrm{F}_{\text {ref }}=0.18$ (TMGC meeting in December, 2002). When stock conditions are poor, fishing mortality rates should be further reduced to promote rebuilding.

## ESTIMATION AND DIAGNOSTICS

## Calibration of Virtural Population Analysis (VPA)

Evaluation of the state of the resource was based on results from an age structured analytical assessment (Virtual Population Analysis, VPA), which used fishery catch statistics and sampling for size and age composition of the catch from 1978 to 2010 (including discards). The VPA was calibrated to trends in abundance from three research bottom trawl survey series: NMFS spring, NMFS fall and DFO.

Two consensus VPA model formulations were established during the benchmark assessment review in 2009 (O'Brien and Worcester, 2009; Wang et al., 2009a). The survey abundance indices were split in 1993-1994 for both model formulations. Natural mortality (M) was fixed at 0.2 for all the ages in all years for the "split M 0.2 " model and was fixed at 0.5 for ages $6+$ in years after 1994 for the "split M 0.5" model. These model formulations will be referred to as "split M 0.2 " and "split M 0.5 " model in this document. The adaptive framework, ADAPT, (Gavaris 1988) was used for calibrating the virtual population analysis with the research survey data for both the "split M 0.2 " and "split M 0.5 " formulations. Computational formulae used in ADAPT are described by Rivard and Gavaris (2003a). The data used in the model were:
$C_{a, t}=$ catch at age for ages $\mathrm{a}=1$ to $10+$ and time $t=1978$ to 2010, where $t$ represents the year during which the catch was taken
$I_{1, a, t}=$ DFO survey for ages $\mathrm{a}=1$ to 8 and time $t=1986.17,1987.17 \ldots$ 1992.17, 1993.17
$I_{2, a, t}=$ DFO survey for ages $a=1$ to 8 and time $t=1994.17,1995.17 \ldots 2010.17,2011.00$
$I_{3, a, t}=$ NMFS spring survey (Yankee 41) for ages $a=1$ to 8 and time $t=1978.28,1979.28$, 1980.28, 1981.28
$I_{4, \mathrm{a}, \mathrm{t}}=$ NMFS spring survey (Yankee 36), for ages $\mathrm{a}=1$ to 8 and time $t=1982.28,1983.28 \ldots$ 1992.28, 1993.28
$I_{5, \mathrm{a}, \mathrm{t}}=$ NMFS spring survey (Yankee 36), for ages $\mathrm{a}=1$ to 8 and time $t=1994.28,1995.28 \ldots$ 2010.28, 2011.00
$I_{6, a, t}=$ NMFS fall survey, ages $a=1$ to 5 and time $t=1978.79,1979.79 \ldots 1992.79,1993.79$
$I_{7, a, t}=$ NMFS fall survey, ages $a=1$ to 5 and time $t=1994.79,1995.79 \ldots 2009.79,2010.79$.
The population was calculated to the beginning of 2011; therefore the DFO and NMFS spring survey indices for 2011 were designated as occurring at the beginning of the year, i.e. 2011.00. The benchmark formulations assumed that observation errors for the catch at age data were negligible. Observation errors for the abundance indices at age were assumed to be independent and identically distributed after taking natural logarithms of the values. Zero observations for abundance indices were treated as missing data as the logarithm of zero is not defined. Fishing mortality on age 9 for 1978 to 2010 was assumed to be equal to the population weighted average fishing mortality on ages 7 and 8 .

Estimation was based on minimization of the objective function:
$\sum_{s, a, t}\left(\ln I_{s, a, t}-\left(\hat{\kappa}_{s, a}+v_{a, t}\right)\right)^{2}$, where $s$ indexes survey.

The estimated model parameters were:
$V_{a, t}=\ln N_{a, t}=\ln$ population abundance for $\mathrm{a}=2$ to 9 at time $t=2011$
$K_{1, a}=\operatorname{In}$ DFO survey catchability for $\mathrm{a}=1$ to 8 at time $\mathrm{t}=1986$ to 1993
$K_{2, a}=\ln$ DFO survey catchability for $\mathrm{a}=1$ to 8 at time $\mathrm{t}=1994$ to 2010 and $\mathrm{a}=2$ to 8 at time $\mathrm{t}=2011$
$K_{3, a}=\operatorname{In}$ NMFS spring survey (Yankee 41) catchability for ages $a=1$ to 8 at time $t=1978$ to 1981
$K_{4, a}=\operatorname{In}$ NMFS spring survey (Yankee 36) catchability for ages $a=1$ to 8 at time $t=1982$ to 1993
$K_{5, a}=\operatorname{In}$ NMFS spring survey (Yankee 36) catchability for ages $a=1$ to 8 at time $t=1993$ to 2010 and $\mathrm{a}=2$ to 8 at time $\mathrm{t}=2011$
$K_{6, a}=\operatorname{In}$ NMFS fall survey catchability for ages $a=1$ to 5 at time $t=1978-1993$
$K_{7, a}=\ln$ NMFS fall survey catchability for ages $\mathrm{a}=1$ to 5 at time $\mathrm{t}=1994-2010$.
Statistical properties of the estimators were determined using conditional non-parametric bootstrapping of model residuals (Efron and Tibshirani 1993, Rivard and Gavaris 2003a).

## A. "split M 0.2" model

For population abundance estimates at the beginning of 2011, age 2 exhibited the largest relative bias of $9 \%$ followed by the estimate at age 9 which showed a relative bias of $8 \%$. The relative bias for other ages ranged between $4 \%$ and $7 \%$. The relative error ranged between $34 \%$ and $60 \%$ (Table 14). Survey catchability ( $q$ ) at age progressively increased until about age 6 for DFO 1994-2011 and age 5 for NMFS spring Y36 1994-2011 survey (Figure 25). Compared with the survey catchability prior to 1994, both DFO and NMFS spring survey catchability has abruptly increased starting at about age 3 . Survey catchability at age for the NMFS fall survey was very low (Figure 25).

## B. "split M 0.5" model

For population abundance estimate at the beginning of 2011, age 2 exhibited the largest relative bias of about $9 \%$, whilst for other ages/times it ranged between $2 \%$ and $5 \%$. The relative error ranged between $31 \%$ and $45 \%$ (Table 15). This model tended to have a smaller relative error and bias than the "split M 0.2 " model. Survey catchability (q) at age progressively increased until about age 5 for the DFO 1994-2011 survey and the NMFS spring Y36 1994-2011 survey, remaining flat at older ages (Figure 25). Compared with the survey catchability prior to 1994, both DFO and NMFS spring survey catchability after 1994 has increased starting at about age 3. Survey catchability at age for the NMFS fall survey was very low (Figure 25).

## Comparisons

The overall fit of model estimated biomass to the DFO, NMFS spring and NMFS fall surveys was generally consistent with the survey trends after 1994. VPA estimates at older ages were higher than survey observations for 2009 and 2011 (Figure 26). There were still residual patterns for both models, which suggested some strong year effects (Figure 27).

Retrospective analyses were used to detect any patterns of consistently overestimating or underestimating fishing mortality, biomass and recruitment relative to the terminal year estimates. Both model formulations exhibited similar patterns, with the "split M 0.2" model exhibiting a slightly stronger retrospective pattern than the "split M 0.5" model. The 2003 and 2005 year classes were initially overestimated at age 1, whilst the 2002, 2006, 2007 and 2008 year classes were initially underestimated at age1. There was a tendency to initially overestimate $3+$ biomass and underestimate fishing mortality in recent years, and the patterns appear stronger in the 2011 assessment compared to the 2009 and 2010 assessment
(Figures 28 and 29). The average Mohn's rho from seven year peels (Mohn 1999) calculations showed an overestimate of $3+$ biomass of approximately 0.88 for the "split M 0.2 " model and approximately 0.62 for the "split M 0.5 " model, and the F rho was -0.39 for the "split M 0.2 " model and -0.31 for the "split M 0.5 "model (Table 16). If the $3+$ biomass in 2011 was adjusted to account for the retrospective pattern, it would be about $53 \%$ for the "split 0.2 " model and $62 \%$ for the ""split 0.5 " model by applying the multiplier $1 /(1+$ rho $)$ to the model estimate.

Fishing mortality calculated from the "split M 0.5" model was more consistent with the perception about changes in effort associated with more restrictive management measures (Figure 30). The model output was more in line with recent management measures and observed catch. Both models indicated flat fishing partial recruitment except for the 10+ group (Figure 31).

## STATE OF RESOURCE

Adult population biomass (ages 3+) declined substantially from about 50,000 mt in 1990 to below 10,000 mt in 1995, the lowest year observed at that time (Table 19 and 22, Figure 32), regardless of model formulation. In the "split M 0.2 " model, biomass subsequently fluctuated between $5,100 \mathrm{mt}$ and $10,100 \mathrm{mt}$ before decreasing to $3,100 \mathrm{mt}$ in 2005, then slightly increased until 2011, when the biomass decreased again to $3,288 \mathrm{mt}$ ( $80 \%$ confidence interval: $2,769 \mathrm{mt}-$ $4,217 \mathrm{mt}$ ). In the "split M 0.5 " model, biomass since 1995 fluctuated between $6,700 \mathrm{mt}$ and $12,600 \mathrm{mt}$ before decreasing to $4,200 \mathrm{mt}$ in 2005. The estimated biomass was $5,088 \mathrm{mt}(80 \%$ confidence interval: $4,274 \mathrm{mt}-6,291 \mathrm{mt}$ ) at the beginning of 2011. Production in 2005 was largely due to the recruitment of the 2003 year class, and the increases in 2006-2010 were due to growth of this year class (Figure 33). Lower weights-at-age in the population in recent years and generally poor recruitment have contributed to the lack of sustained rebuilding.

Recruitment at age 1 has been low in recent years (Table 17 and 20, Figure 32). Since 2000, the 2003 year class ( 2.8 million fish from the "split M 0.2 " model and 4.1 million fish from the "split M 0.5 " model) has shown the highest recruitment observed by either model, but it was less than half of the average (about 10 million) during 1978-1990, when the productivity was considered to be higher (Figure 33). Recruitment for the 2002 and 2004 year classes was the lowest on record in both models. The 2006 year class at age 1 ( 1.6 million from the "split M 0.2 " model and 1.9 million from the "split M 0.5 " model) was close to half the strength of the 2003 year class. Initial indications were that the 2007, 2008, and 2009 year classes were similar in strength to the 2000 year class, which was only about $10 \%$ of the 1978-1990 average recruitment in both models. The current biomass is well below $30,000 \mathrm{mt}$ where recruitment has historically been poor (Figure 34). Recruitment indices from the bottom trawl surveys for the 2010 year class were higher than those for recent year classes although they were not estimated in the VPA.

Fishing mortality (population number weighted average) for ages 4-9 was higher prior to 1994 (Table 18 and 21, Figure 35). F declined in 1995 to $\mathrm{F}=0.36$ for the "split M $0.2^{\text {" model and }}$ to 0.24 for the "split M 0.5 " model due to restrictive management measures. F then fluctuated between 0.38 and 0.85 for the "split M0.2" model and 0.26 and 0.59 for the "split M 0.5 " model. F in 2010 was estimated to be 0.41 from the "split M 0.2 " model and 0.25 from the "split M 0.5 " model. Both models show recent reductions in F, but fishing mortality is consistently above the reference level $\mathrm{F}_{\text {ref }}$ of 0.18 .

Yield exceeded surplus production during the early 1990s (Figure 36). Surplus production since the mid 1990s has remained considerably lower than that prior to 1990. Growth of ages 2 to 10
has typically accounted for the greatest percentage of the production (Figure 33). Occasionally, a strong incoming year-class at age 2 makes a greater contribution to production. The 2003 year class made such a contribution in 2005. In 2009 and 2010, yield exceeded surplus production (Figure 36).

## PRODUCTIVITY

Recruitment, age structure, fish growth and spatial distribution reflect changes in the productive potential. Recruitment, while highly variable, has generally been higher when ages 3+ biomass exceeded $30,000 \mathrm{mt}$ (Figure 34). The current biomass is well below $30,000 \mathrm{mt}$. The number of recruits per spawner has not increased when the biomass has been low (Figure 37). This lack of compensation hampers stock rebuilding. In both absolute numbers and percent composition, the population age structure since 1995 displays a very low proportion of older $7+$ age groups compared to the 1980s (Figure 38). Average weight at length, used to reflect condition, has been stable in the past, but has started to decline in recent years. The declines in length and weight at age from the early 1990s have hampered biomass rebuilding. Weights at age in the 2010 fishery continued to decline for all ages except for age 3 (Figure 14). The spatial distribution patterns observed during the most recent bottom trawl surveys showed that adult cod were distributed in a similar manner to the average over the past decade (Figures 17 to 19). Resource productivity is currently very poor due to low recent recruitment and low weights at age compared to the 1980s.

## OUTLOOK

This outlook is provided in terms of consequences with respect to the harvest reference points for alternative catch quotas in 2012 (Gavaris and Sinclair 1998, Rivard and Gavaris 2003b). Uncertainty about standing stock generates uncertainty in forecast results which is expressed here as the risk of exceeding $\mathrm{F}_{\text {ref }}=0.18$. The risk calculations assist in evaluating the consequences of alternative catch quotas by providing a general measure of the uncertainties. However, they are dependent on the data and model assumptions and do not include uncertainty due to variations in weight at age, partial recruitment to the fishery, natural mortality, systematic errors in data reporting or the possibility that the model may not reflect stock dynamics closely enough.

For projections, the 2008-2010 average values were assumed for the fishery weight at age in 2011-2012. The 2009-2011 survey average values were assumed for the beginning of year population weights at age in 2012-2013. However, for the slower growing 2003 year class, fishery weights at age 8 in 2011 and age 9 in 2012 and beginning of year weights at age 9 in 2012 and at age 10 in 2013 were obtained from cohort regressed values under the assumption of a linear regression relationship between age and weight at age. The 2006-2010 average values were assumed for the partial recruitment pattern in 2011-2012 (Table 23). The 20062010 average value of recruitment at age 1 from each model was used for 2011-2013 projections. Catch in 2011 was assumed to be equal to the $1,050 \mathrm{mt}$ quota, and $\mathrm{F}=0.18$ in 2012. Deterministic projection (Table 24) and stochastic projections (Figures 39-40) are provided from each of the model results.

## A. "split M 0.2" model

A combined Canada/USA catch of 525 mt in 2012 corresponds to a low (25\%) probability that F will exceed $\mathrm{F}_{\text {ref }}=0.18$, whereas catches of 600 mt correspond to a neutral (50\%) probability and
catches of 700 mt correspond to a high (75\%) probability that F will exceed $\mathrm{F}_{\text {ref }}$ (Figure 39). Catches of $1,350 \mathrm{mt}$ will result in a neutral risk (50\%) that the 2013 adult biomass (4+) will be lower than the 2012 adult biomass, a catch of $1,000 \mathrm{mt}$ will result in a neutral risk (50\%) that 2013 adult biomass will not increase by $10 \%$ and a catch of 650 mt will result in a neutral risk (50\%) that 2013 adult biomass will not increase by 20\% (Figure 40).

## B. "split M 0.5" model

A combined Canada/USA catch of 825 mt in 2012 corresponds to a low (25\%) probability that F will exceed $\mathrm{F}_{\text {ref }}=0.18$, whereas catches of 925 mt correspond to a neutral ( $50 \%$ ) probability and catches of $1,025 \mathrm{mt}$ correspond to a high ( $75 \%$ ) probability that F will exceed $\mathrm{F}_{\text {ref }}$ (Figure 39). Catches of 900 mt will result in a neutral risk (50\%) that the 2013 adult biomass (4+) will be lower than the 2012 adult biomass and a catch of about 300 mt will result in a neutral risk (50\%) that the 2013 adult biomass will not increase by $10 \%$. Even at 0 catch there is a more than $50 \%$ probability that 4+ biomass will not increase by 20\% (Figure 40).

The benchmark methods do not account for the retrospective pattern in projections. If the magnitude of the retrospective pattern was accounted for, short term projections for catch would be decreased for both models.

While management measures have resulted in decreased exploitation rates since 1995, fishing mortality has remained above $F_{\text {ref }}$ and adult biomass has fluctuated at a low level without any appreciable rebuilding. The continuing poor recruitment since the early 1990s is an important factor for this lower productivity. The 2003 year class made a substantial contribution to the fishery and population biomass. It is projected to be only a small component in the fishery catch in 2011-2012 and population biomass in 2012-2013 (Figures 41-42, Table 24). With the passing of the 2003 year class through the population, rebuilding will not occur without improved recruitment.

## SPECIAL CONSIDERATIONS

The management advice and performance since 1999 are summarized in Table 25, which was kindly provided by Tom Nies (staff member of the New England Fishery Management Council, NEFMC). The Transboundary Resource Assessment Committee (TRAC) advice, TMGC quota decision, actual catch, and realized stock conditions for eastern Georges Bank cod are compared. The inconsistency of TRAC advice in the past with the realized stock conditions from the recent assessment was mainly due to the assessment model changes after the 2009 benchmark assessment, and the retrospective pattern in the assessment also accounted for part of this inconsistency.

Cod and haddock are often caught together in groundfish fisheries, although they are not necessarily caught in proportion to their relative abundance because their catchabilities to the fisheries differ. Due to the higher haddock quota, discarding of cod may be high and should be monitored; at-sea observers are an essential component of this monitoring. Modifications to fishing gear and practices, with enhanced monitoring, may mitigate these concerns.

Mechanisms that explain changes in either survey catchability or natural mortality could not be established. Changes in natural mortality could be aliasing "missing" catch, particularly during the regulatory and reporting changes of the mid 1990s. It could also be aliasing emigration or imperfect designation of the boundaries for this component, though an excess of larger/older fish is not apparent in adjacent cod components.

There is no strong evidence to determine which of the two benchmark methods provides a better scientific basis for fishery management; both models should be considered when setting catch levels. The range of stock perceptions and outlooks from the two models reflect the substantial uncertainty in the assessment. Despite these uncertainties, all assessment results indicate that low catches are needed to promote rebuilding and/or prevent further decline.

2009 TAC=1,173mt;
    Winter fishery from Jan. }1\mathrm{ to Feb. 21, 2009;
    At sea observer coverage 23% by weight of the mobile gear fleet landings and 15% by weight of the
        fixed gear landings;
    Spawning protocol: 30% of maturity stages at 5 to 7.
2010 TAC=1,350mt;
    Winter fishery from Jan. }1\mathrm{ to Feb. 8, 2010;
    At sea observer coverage 18% by weight of the mobile gear fleet landings and 6% by weight of the
        fixed gear landings;
    Spawning protocol: 30% of maturity stages at 5 to 7.
```

## 2b. USA Management History

| 2001 | November 6: Daily haddock possession limit removed(maximum 50,000lbs.-trip). |
| :---: | :---: |
| 2002 | May: Interim rule as a result of FW 33 lawsuit settlement agreement. Continuation of most measures from previous frameworks. DAS: 15 hour minimum charged for all trips over 3 hours,Vessels limited to $25 \%$ of allocation May 1 through July 31, 2002 (only). Prohibition on front-loading DAS. Minimum size: Cod 22". Gear: GOM Regulated Mesh Area (RMA): 6.5 in. diamond or square codend minimum, $6.5^{\prime \prime}$ mesh for trip gillnets, 6.5 inch mesh standup (roundfish) or 7 " mesh tiedown (flatfish) for day gillnets. All areas:day gillnets limited to 50 standup/100 tiedown nets. Hook gear: de-hooking devices with spacing of less than 6" prohibited. Recreational: Cod minimum size 23". All areas- private recreational limited to 10 cod. Possession limits: Remain the same. June: Revised interim rule:Minimum size: Cod 19", Gear: Hook: Requirement for 6 " spacing for de-hooking gear removed. Aug: Emergency rule implementing FW 33 lawsuit settlement agreement: DAS: DAS allocation for each permit reduced 20 percent from maximum used \FY 1996-2000 (est 71,218 allocated, including carry-over). DAS counted by the minute, except for day gillnet vessels (15 hour minimum). (This change reverted to DAS counting in effect in FY 2001). Prohibition on front-loading DAS clock. Minimum size: Cod 22". Gear: Trawl: GOM/GB RMAs: 6.5" diamond or square codend minimum; Hook: GB: 3,600 rigged hooks Closures: Add GB seasonal closure areas, May - Blocks 80, 81, 118, 119, 120 (south of 42-20N). Recreational: Cod/haddock: 23" minimum size. Party/charter: GOM RMA: April-November, 10 cod/haddock combined per person, Dec-Mar - 10 cod/haddock combined, no more than 5 cod per person per trip. Private: GOM RMA: December-March $10 \mathrm{cod} / \mathrm{haddock}$ combined, no more than 5 cod. Commercial minimum size increased to 22 " ( 55.9 cm ) |
| 2003 | July: Final emergency rule implementing FW 33 lawsuit settlement agreement. Recreational: Other areas (including GB ):10 cod/haddock combined. |
| 2004 | May: Implementation of Amendment 13. Measures based on emergency rule and measures in effect prior to interim rule. Special Management Programs: US/Canada Area: hard TAC on cod, Cod possession limit: $500 \mathrm{lbs}-\mathrm{DAS} / 5,000 \mathrm{lbs}-t r i p$, not more than 5 percent of catch. No DAS charged to/from SAs 561, 562. VMS required in U.S/Canada Management Area; only Category A DAS Daily catch report via VMS (catch\&discard) ;Haddock separator trawl; flatfish net. October: Closure of SAs 561 and 562 to all fishing on a multispecies DAS. November: Framework Adjustment 40A. Eastern US/CA Area Haddock SAP Pilot Program Access to northern corner of CAll and adjacent area to target haddock using separator trawl. Season: May 1 through December 31. Authorized use of Category B DAS. |
| 2005 | January: Eastern US/CA reopened, Cod trip limit of 5,000 lbs./trip in Eastern US/CA area. Vessels fishing in Eastern US/CA area must use haddock separator trawl. April: Eastern US/CA area closed until April 30, 2005. May: Eastern US/CA Area reopens at beginning of fishing year. Measures revert to those implemented May 1, 2004. July: NE multispecies DAS vessels are limited to one trip per month in the Eastern US/CA area. Multispecies DAS vessels are prohibited from fishing in the Category B (regular) DAS program in the GB cod stock area through July 31. NE multispecies trawl vessels are required to use haddock separator trawl when fishing in the Eastern US/CA area. August : Eastern US/CA area is closed to all limited access multispecies DAS vessels because 90 percent of the GB cod TAC for the area is projected to be harvested. |
| 2006 | Implementation of an emergency rule to reduce fishing mortality on groundfish stocks while FW 42 is reviewed. Special Management Programs: Eastern US/Canada haddock SAP: Opening delayed until August 1. Category B (regular) DAS Program: Renewed, with vessels restricted to the US/CA Area, required to use a haddock separator trawl, limited to 500 days May-June, 1,000 days in other quarters, low trip limits on stocks of concern. Other: Vessels allowed to fish inside and outside the eastern US/CA area on the same trip. June: All trawl vessels fishing in the eastern US/CA area required to use a haddock separator trawl. November: Implementation of FW 42 - Major regulatory changes: Special Management Programs: US/Canada Area: Opening delayed until August 1. Prohibition on discarding legal sized fish. Category B (regular) DAS Program: Renewed for all areas. Trawl vessels required to use a haddock separator trawl, limited to 500 days May-June, 1,000 days in other quarters, low trip limits on stocks of concern. Prohibition on discarding legal sized fish. Other: (same as emergency rule) Vessels allowed to fish inside and outside the eastern US/CA area on the same trip. |
| 2007 | March: Trawl vessels fishing in the eastern US/CA area allowed to use either a haddock separator trawl or a flounder net. April: Eastern U.S./Canada area closed to limited access multispecies vessels (through April 30, 2007). May: Eastern U.S./Canada area reopens. June: Eastern US/CA area is closed to limited access multispecies DAS vessels due to cod catch.. October: The Eastern US/CA area is opened to limited access multispecies DAS vessels. The GB cod possession limit is 1,000 lb/trip for all vessels declared into the Eastern US/CA Area or the Eastern US/CA Area SAP. |
| 2008 | May: Eastern U.S./Canada area opening delayed until August 1, 2008 for vessels fishing with trawl gear. Eastern U.S./Canada area opened to longline gear but with a cod cap of 33.4 mt . August: Eastern U.S./Canada management area opens to all vessels. U.S./Canada Haddock SAP opens. Haddock rope trawl (later called the Ruhle trawl, previously called the eliminator trawl) approved for use in the Category B (regular) DAS program and the U.S./Canada Haddock SAP. September: Ruhle trawl authorized for use in the Eastern U.S./Canada management area. November: Landing limit for Eastern GB cod increased to 1,000 lbs./DAS up to a maximum of 10,000 lbs./trip (applies to cod caught in the Eastern U.S./Canada management area). |
| 2009 | January 26: NE Multispecies regulations adopted by FW 42 suspended as a result of a court order. No clear explanation of what measures are affected. <br> February 13: NMFS identifies following measures as NOT impacted by the court order to suspend measures adopted by FW 42: <br> - Recordkeeping and reporting requirements <br> - Gear restrictions <br> - DAS allocations |

```
- Time and area closures
- Minimum fish sizes
- SAPs
- Recreational measures
- Cape Cod Hook Sector
- Some possession limits (GOM cod }800\textrm{lbs}\mathrm{ DAS-4,000 lbs/trip,, GB cod 1,000 lbs./DAS - 10,000 lbs./trip,
US/CA area trip limits
Confusion continues on what regulations are not in effect.
February 17: Federal court rescinds decision to suspend FW 42 measures and limits suspension to
differential DAS counting areas in the GOM and SNE/MA areas, and authorizes submission of DAS leasing
requests through March 31, }2009\mathrm{ (vice normal March 1 deadline for such requests).
March 9: Eastern GB cod landing limit reduced to 500 lbs./DAS - 5,000 lbs./trip.
April 16: Eastern USICA area closed until May }1
May 1: Interim rules in effect to reduce overfishing on multispecies stocks until Amendment 16
implemented. Major changes:
DAS: DAS allocations reduced according to Amendment }13\mathrm{ schedule. Category A DAS are reduced to 45 percent of
the permit's DAS baseline, an 18 percent reduction from the previous year's allocations. Differential DAS area
increased in SNE/MA.
Possession limits: GB cod: 1,000 lbs./DAS-10,000 lbs./trip (eastern US/CA area }500\textrm{lbs./DAS-5,000 lbs./trip).
Special Management Programs: US/Canada Area: Opening delayed until August }1\mathrm{ for trawl vessels. SNE/MA winter
flounder SAP suspended. State waters winter flounder exemption eliminated. CAI Hook Gear Haddock SAP expanded
to May }1\mathrm{ to January 31, area increased, no separation between common pool and sector participants.
Recreational Measures: GB cod bag limit of n10 cod per person per day for party/charter vessels;
Other: Conservation tax removed from DAS transfers.
May 6: Limited access general category scallop fishery closed to IFQ vessels until June 1.
June 26: eastern USICA Area closed to all vessels until August }1\mathrm{ (including fixed gear vessels) to prevent exceeding
first quarter GB cod TAC.
June 29: CAll Scallop Access Area closed to prevent exceeding GB yellowtail flounder cap.
July 19: Limited access general category scallop fishery closed to IFQ vessels until September 1.
September 15: Limited access general category scallop fishery closed to IFQ vessels until December 1.
September 17: Use of flounder trawl net prohibited when fishing in the Eastern US/CA area.
November 20: In the USICA management area, trawl vessels required to use a haddock separator trawl or Ruhle
trawl south of 41-40N latitude. Any vessel fishing in this area and other areas cannot use any other gear on the same
trip. Vessels fishing north of 41-40N for the entire trip can use any legal gear.
2010 January 12: Limited access general category scallop fishery closed to IFQ scallop vessels
    March 1: Limited access general category scallop IFQ program opens. Scallop fishery Elephant Trunk and
    DELMARVA Access Areas open.
    March 11: All multispecies vessels fishing on a Category A DAS allowed to use any legal trawl gear in the Western
    US/CA Area (statistical areas 522,525) (lifts restrictions adopted November 20, 2009).
    April 13: All multispecies vessels fishing on a Category A DAS allowed to use a flounder trawl net in the Eastern
    US/CA area.
    April 20: Eastern US/CA area (statistical areas 561,562) closed to multispecies vessels and harvest, possession, and
    landing of GB yellowtail flounder from entire US/CA area (statistical areas 522,525,561,562) prohibited.
    May 1: Implementation of Amendment 16 and Framework 44. Expansion of sector management program to majority of
    the fishery. Major revisions to common pool measures for permitted vessels not in sectors. Adoption of additional at-
    sea and dockside monitoring requirements for sector vessels, and new reporting requirements for other vessels.
    Adoption of new US/CA area TACs. Adoption of annual catch limit (ACL) and accountability measures (AM) for most
    stocks. Key elements:
    Sector Management: Vessels in sectors subject to hard TACs for most stocks, increased at-sea monitoring (targeting
    38 percent of trips), dockside monitoring; not subject to trip limits, groundfish DAS limits. Permits committed to sectors
    account for 94 percent or more of available catch except for GOM WFL (84 pct) and SNE/MA YTF (76 pct), and
    SNE/MA WFL (0%). Total permits committed to sectors: 762. Sector vessels required to retain all legal-sized fish
    (except limited to one Atlantic halibut, and the five species prohibited). Sectors required to stop fishing in a stock area
    when a quota (Annual Catch Entitlement, or ACE) for a stock in the area is caught.
    Common pool: Only a small portion of the ACL available to common pool vessels. Major elements of common pool
    regulations:
    DAS: Category A DAS allocations reduced to 27.5 percent of the Amendment 13 baseline allocation. All DAS charged
    in 24 hour increments.
    Possession limits: GB cod: 2,000 lbs./DAS-20,000 lbs./trip (eastern US/CA area }500\textrm{lbs./DAS-5,000 lbs./trip).
    Restricted Gear Areas: Areas near CAI and off SNE created to reduce flatfish catches; limited to separator/Ruhle
    trawls, rope trawl, certain gillnets in these areas.
    Special Management Programs: US/Canada Area: Opening delayed until August }1\mathrm{ for trawl vessels. Prohibition on
    discarding legal sized fish. SNE/MA winter flounder SAP suspended. State waters winter flounder exemption
    eliminated. CAI Hook Gear Haddock SAP expanded to January 31, area increased, no separation between common
    pool and sector participants. CAll yellowtail flounder -haddock SAP: SAP opening authorized to target haddock (not
    GB yellowtail flounder_ subject to specific gear requirements. Opening date August 1.
    Adjustments: RA authorrized to make in-season adjustments to trip limits and DAS counting rates.
    DAS Leasing and Transfers: Permits in CPH category allowed to participate in these programs. No conservation tax
    on transfers.
    May 27: Changes to common pool trip limits:
    GOM haddock: 1,000 lbs./trip
```

```
GB haddock: 10,000 lbs./trip
GOM winter flounder: }250\mathrm{ lbs./trip
GB winter flounder: 1,000 lbs./trip (offshore)
GB yellowtail flounder: 1,000 lbs./trip (offshore)
July 15: Pollock ACL revised; increased to 16,553 mt.
July 30: Changes to common pool measures:
GB yellowtail flounder: Selective trawl gear required in Eastern US/CA area and Western US/CA area south of 41-
40N.
August 6: Changes to common pool measures:
Pollock trip limit removed
Witch flounder: }130\textrm{lbs}./tri
August 31: Common pool DAS counting rate set to 2:1 for GOM and GB differential DAS areas.
September 22: Changes to common pool measures:
GB yellowtail flounder: }100\mathrm{ lbs./trip
White hake: 100 lbs./DAS - 500 lbs./trip
US/CA area: Selective trawl gear required to entire US/CA management area
October 18: Handgear A cod trip limit reduced to }50\textrm{lbs}/\mathrm{ trip.
```

Table 11. Indices of swept area abundance (thousands) for eastern Georges Bank cod from the NMFS spring survey. Conversion factors to account for vessel and trawl door changes have been applied. During 1973-1981 a Yankee 41 net was used rather than the standard Yankee 36 net.

Figure 6. Landings (wide bars) and sampling (narrow dark bars) of cod by gear and month from the 2010 Canadian bottom trawl (OTB), longline (LL) and gillnet (GN) fisheries on eastern Georges Bank.

Figure 7. Comparison of cod length frequency composition from port and at sea observer sampling of the 2010 Canadian bottom trawl (OTB), longline (LL) and gillnet (GN) fisheries on eastern Georges Bank.

Figure 8. Cod catches at length by gear from the 2010 Canadian fisheries on eastern Georges Bank.

Figure 9. Cod landings and discards at length from the 2010 Canadian fisheries on eastern Georges Bank.

Figure 1. Cod landings and discards at length from the 2010 USA fisheries on eastern Georges Bank.

Figure 11. Catch length frequency composition from the 2010 Canadian and USA fisheries on eastern Georges Bank.

Figure 12. Catch at age in numbers (left) and weight (right) for landings and discards of cod from the 2010 eastern Georges Bank fisheries.

Figure 13. Total catch at age (numbers) of cod (left) and proportion of catch at age from eastern Georges Bank for 1978 to 2010. The bubble area is proportional to the magnitude. The light green circles are the 2003 year class and the light blue circles are the 2006 year class.

Figure 14. Average weights at ages 2 to 9 of cod from the eastern Georges Bank fishery, 1978 to 2010.

Figure 15. Stratification used for the NMFS surveys. The eastern Georges Bank management unit is indicated by shading.

Figure 16. Stratification used for the DFO survey. The eastern Georges Bank management unit is indicated by shading.

Figure 17. Spatial distribution of age 3+ cod on eastern Georges Bank from the DFO survey for 2011 (right panel) compared to the average for 2001 to 2010 (left panel).

Figure 18. Spatial distribution of age $3+$ cod on eastern Georges Bank from the NMFS spring survey for 2011 (right panel) compared to the average for 2001-2010 (left panel).

Figure 19. Spatial distribution of age 3+ cod on eastern Georges Bank from the NMFS fall survey for 2010 (right panel) compared to the average for 2000-2009 (left panel).

Figure 20. Survey abundance at age (numbers) of eastern Georges Bank cod. The bubble area is proportional to magnitude within each survey. Conversion factors to account for changes in door type, net and survey vessel were applied to the NMFS surveys. The NMFS spring survey was conducted using a modified Yankee 41 during 1978 to 1981 (lighter bubbles). The 2003 year class is identified with green bubbles whilst the 2006 year class is identified with yellow bubbles, the fuschia bubbles show 2010 year class.

Figure 21. Survey biomass indices (ages 1+) for eastern Georges Bank cod from the DFO spring and NMFS spring and fall surveys.

Figure 22. Survey biomass indices for ages $2-3$, ages $4-6$, and ages $7-8$ for the DFO spring and NMFS spring and fall surveys. The black line represents the smoothed trends for different age groups of eastern Georges Bank cod.

Figure 23. Beginning of year weight at age of eastern Georges Bank cod from DFO and NMFS spring surveys. The lines show the smoothed values using LOESS method.

Figure 24. Smoothed condition factor (Fulton's K by age) for eastern Georges Bank cod from the DFO survey.

Figure 25. Survey catchability (q) for the DFO, NMFS spring and NMFS fall surveys from the "split M 0.2 " and "split M 0.5 " model formulations.

Figure 26. Assessment biomass trends comparison with DFO, NMFS spring and NMFS fall surveys.

Figure 27. Residuals by year and age group from survey indices for eastern Georges Bank cod. Solid bubbles indicate positive values, open bubbles indicate negative values and the bubble area is proportional to magnitude. The NMFS spring survey was conducted using a modified Yankee 41 from 1978 to 1981 (pale blue bubbles). The upper figures are from the "split M 0.2 " model and the lower figures are from the "split M 0.5 " model.

Figure 28. Retrospective patterns for recruitment at age 1,3+ biomass and fishing mortality of eastern Georges Bank cod for the "split $M 0.2$ " and "split M 0.5" models.

Figure 29. Relative retrospective patterns for recruitment at age 1, 3+ biomass and fishing mortality of eastern Georges Bank cod for the "split M 0.2" and "split M 05" models.

Figure 30. Average fishing mortality (F) for eastern Georges Bank cod in 3 time series blocks (19781993, 1994-2005, 2006-2010) from the "split M 0.2 " (left) and "split M 0.5 (right) model formulations.

Figure 31. The fishing partial recruitment (PR) for eastern Georges Bank cod in 3 time series blocks (1978-1993, 1994-2005, 2006-2010) from the "split M 0.2 " (left) and "split M 0.5 (right) model formulations.

Figure 32. Adult biomass (ages $3+$ ) and year class abundance at age 1 for eastern Georges Bank cod.

Figure 33. Components of annual production for eastern Georges Bank cod attributable to growth of ages 2 to 10 and to the amount contributed by incoming year classes at age 2 .

Figure 34. Relationship between adult biomass (ages 3+) and recruits at age 1 for eastern Georges Bank cod. The green and red arrows indicate the 2009 year class at age 1 from the "split M 0.2 " and "split M 0.5 " model, respectively.

Figure 35. Average fishing mortality rate at ages 4 to 9 and catches for eastern Georges Bank cod. The established fishing mortality threshold reference, $\mathrm{F}_{\text {rei }}=0.18$, is indicated.

Figure 36. Surplus production of eastern Georges Bank cod compared to harvested yield.

Figure 37. Recruitment rate (R/3+biomass) for eastern Georges Bank cod.

Figure 38. Population numbers from the 2011 assessment of eastern Georges Bank cod. Bubble sizes are proportional to population numbers. Light green bubbles are the 2003 year class and light blue bubbles are the 2006 year class.

Figure 39. Risk of 2012 fishing mortality exceeding $\mathrm{F}_{\text {ref }}=0.18$

Probability $B_{2013}$ at age 4+ will not increase by $\mathbf{1 0 \%}$

Probability $B_{2013}$ at age 4+ will not increase by 20\%

Figure 40. Risk of 2013 biomass not increasing, not increasing by $10 \%$ or $20 \%$ from 2012 for alternative total yields of eastern Georges Bank cod.

Figure 41. Projected fishery catch age composition of eastern Georges Bank in 2011 and 2012 if the catch is $1,050 \mathrm{mt}$ in 2011 and $\mathrm{F}_{2012}=0.18$, the year label represent the year class.

## APPENDIX A: Discards of Cod from the 2010 Canadian Groundfish Fishery on Eastern Georges Bank

## Data and Methods

Discards of cod from the Canadian groundfish fishery were estimated using the ratio of sums estimator methods described by Gavaris et al. (2007b). Landings of cod and haddock for 2010 were obtained from the fisheries statistics database maintained by the Maritimes Region of Fisheries and Oceans Canada. Trips were classified as observed or unobserved. Following Gavaris et al. (2007b), the basic record unit was the aggregate of catches from a trip within each zone, referred to as a sub-trip. Although the use of a separator panel when fishing with a bottom otter trawl on Georges Bank was mandatory in 2010, there were a couple of trips where the panel was not used and these trips were excluded from the analysis. Trips where the observer deployment was for management purposes, rather than routine monitoring, were excluded as these might not be representative.

Virtually all the cod for 2010 were caught in Zones A, B, C and D during fishing targeting for haddock (Table A1, Figure A1). Discards were only derived for the designated fleets targeting haddock. Very few cod were caught by pollock and yellowtail flounder targeted fishing by mobile gear. Sub-trips that sought pollock were identified as those where the catch of pollock exceeded the catch of cod and haddock or observed sub-trips where the declared species sought was pollock. Cod are also taken by limited fisheries using gillnet and handline that direct for cod and there fore are not considered to discard cod. The calculation of discards uses a landings multiplier that is based on ratios of cod to haddock. Factors that are expected to affect the species composition include fishing fleet, fishing ground location and season.

The Canadian quotas are sub-allocated to quota groups. Sub-allocation of shares to quota groups varies by species. Therefore, the quota mix varies substantially by quota group. The quota mix can be an important determining factor in discarding behaviour. Accordingly, fishing fleets were defined by quota groups (Table A2). Generally, quota groups comprise vessels that are similar with respect to size and gear. A quota group's allocation may be fished by vessels smaller than those in the group under the Temporary Vessel Replacement Program (TVRP is a mechanism by which a fleet can contract another fleet to catch their quota without transferring the quota). Almost all of the 2010 catch by the MG 65'-100' and the >100' fleets was taken by vessels less than 65' under the TVRP program.

Zones were defined for Georges Bank based on areas of fishing concentration and homogeneity of species composition (Figure A1). While there appears to be considerable local scale variation in species composition, the zones could not be made smaller given the observer sampling intensity.

The data for each fishing fleet, zone and quarter grouping were analyzed separately to derive an estimator of the landings multiplier that was used to compute discards.

## Results and Discussion

The ratio of sums method was applied to obtain the landings multipliers by fishing fleet, zone and quarter (Table A3). The associated standard errors from the bootstrap analyses are also shown. Bootstrap confidence distributions of the landings multiplier were examined to determine if it could be inferred that discarding occurred. The percentile and bias corrected confidence distributions were generally coincident, indicating that the bias is small. Discards were calculated for cases where the reference landings multiplier of 1 intersected the bias corrected
confidence distribution at a probability of 0.05 or less. Discarding was only inferred for MG<65' and First Nations fleets in quarter 2 and 3, zone B (Figure A2) and MG<65' in quarter 2 and 3, zone C (Figure A3). There was insufficient data to estimate landings multipliers for FG 45-65 and FG 65-100. In total, discards of cod from the Canadian groundfish fisheries on Georges Bank in 2010 were 48 mt (Table A4).

Table A1. Landings ( $m t$ ) of cod used in the analysis of cod discards from the Canadian fisheries on Georges Bank in 2010. Trips targeting pollock, yellowtail and cod were removed. Discards may occur during unobserved fishing. Discard calculations were examined for haddock targeted fishing in Zones A, $B, C$ and $D$ by quarter for the designated fleets (shaded cells).
