## Erratum:

This erratum pertains to corrections required due to incorrect beginning of year population weights at ages 2, 3 and 4 for the 2010 year class which were used for projections and resulted in wrong population biomass estimates for years following 2011. Corrections to text, original versus corrected, in the ABSTRACT, OUTLOOK and SPECIAL CONSIDERATIONS sections and corrections to tables 30, 31, 32 and 33 are indicated below in underlined bold red font:

ABSTRACT<br>Page i, last line of abstract, original: "Adult biomass is projected to increase to $124,600 \mathrm{mt}$ at the beginning of 2013."<br>Page $i$, last line of abstract, corrected:<br>"Adult biomass is projected to increase to $188,700 \mathrm{mt}$ at the beginning of 2013."

## Erratum :

Le présent erratum porte sur les corrections requises en raison d'une mauvaise détermination des poids de la population au début de l'année, aux âges 2, 3 et 4 pour la classe d'âge de 2010, lesquels ont été utilisés pour effectuer des projections et ont alors donné lieu à des estimations de la biomasse de la population erronées pour les années après 2011. Les corrections apportées au texte (la version originale par rapport à la version corrigée) dans les sections SOMMAIRE, PERSPECTIVES et CONSIDÉRATIONS PARTICULIĖRES et les corrections apportées aux tableaux 30, 31, 32 et 33 sont indiquées ci-dessous, en caractères gras et soulignées en rouge :

## SOMMAIRE

Page i, dernière ligne du sommaire, version originale : «On prévoit que la biomasse des adultes sera de 124600 tm au début de 2013. »

Page i, dernière ligne du sommaire, version
corrigée: «On prévoit que la biomasse des adultes sera de 188700 tm au début de 2013. »

## OUTLOOK

Page $12,2^{\text {nd }}$ paragraph, original: "A deterministic projection... The adult biomass will decline to $64,900 \mathrm{mt}$ at the beginning of 2012 as is expected with the passing of the 2003 year class through the population but it will increase to $124,600 \mathrm{mt}$ at the beginning of 2013 when the 2010 year class will be age 3. The 9+ group, of which the 2003 year class is the main component, is expected to comprise $72 \%$ and the 2005 year class $11 \%$ of the 2012 catch biomass (Table 31)."

Page $12,2^{\text {nd }}$ paragraph, corrected: "A deterministic projection... The adult biomass will decline to $64,900 \mathrm{mt}$ at the beginning of 2012 as is expected with the passing of the 2003 year class through the population but it will increase to $188,700 \mathrm{mt}$ at the beginning of 2013 when the 2010 year class will be age 3 . The $9+$ group, of which the 2003 year class is the main component, is expected to comprise $72 \%$ and the 2005 year class $11 \%$ of the 2012 catch biomass (Table 31)."

Page 12, 4th paragraph, original: "An exploratory projection analysis with constant catch of 22, 20, 18, 16 and 14 thousand mt for 2012 and 2013 indicated that the adult biomass would be expected to increase in 2013 and 2014 compared to the current level (2011), however, the fishing mortality rate would exceed Fref for the higher catch levels (Table 32). The sensitivity of the projections to the size of the 2010 year class was examined by reducing it to half of its estimated size. Biomass then decreased from the 2011 level for all constant catch levels examined and the fishing mortality was higher and usually greater than Fref (Table 33). If the lower partial recruitment for the 9+ age group that the model estimates is aliasing higher natural mortality, emigration of older ages outside the management area or some unknown mechanism which results in the unavailability of older
ages to the fishery, Fs would be higher as more of the catch would come from the younger ages.

Page 12, 4th paragraph, corrected: "An exploratory projection analysis with constant catch of $22,20,18,16$ and 14 thousand mt for 2012 and 2013 indicated that the adult biomass would be expected to increase in 2013 and 2014 compared to the current level (2011), however, the fishing mortality rate would exceed Fref for the higher catch levels (Table 32). The sensitivity of the projections to the size of the 2010 year class was examined by reducing it to half of its estimated size. Biomass still increased from the 2011 level for all constant catch levels examined but the fishing mortality was higher and usually greater than $F_{\text {ref }}$ (Table 33). If the lower partial recruitment for the 9+ age group that the model estimates is aliasing higher natural mortality, emigration of older ages outside the management area or some unknown mechanism which results in the unavailability of older ages to the fishery, Fs would be higher as more of the catch would come from the younger ages."

## SPECIAL CONSIDERATIONS

Page 13, $2^{\text {nd }}$ paragraph, original: "The medium term outlook for stock biomass is strongly influenced by the outstanding 2003 and 2010 year classes. As the importance of the 2003 year class diminishes, the 3+ stock biomass will decline in 2012 even for relatively low catch, and it will then increase beginning in 2013 as the 2010 year class recruits. While the catch projection indicates that the 2012 TAC should be less than the 2011 TAC to prevent the fishing mortality rate from exceeding the Fref, the adult biomass would be expected to increase in 2013 and 2014 compared to the current level (2011), even if the 2010 TAC of 22,000 mt was maintained. However, if the 2010 year class turns out to be much smaller than currently estimated (i.e., half the size), a catch equal to the current TAC is likely to result in a decrease in adult biomass in 2014 compared to 2011."

Page 13, $2^{\text {nd }}$ paragraph, corrected: "The medium term outlook for stock biomass is strongly influenced by the outstanding 2003 and 2010 year classes. As the importance of the 2003 year class diminishes, the 3+ stock biomass will decline in 2012 even for relatively low catch, and it will then increase beginning in 2013 as the 2010 year class recruits. While the catch projection indicates that the 2012 TAC should be less than the 2011 TAC to prevent the fishing mortality rate from exceeding the $F_{\text {ref }}$, the adult biomass would be expected to increase in 2013 and 2014 compared to the current level (2011), even if the 2010 TAC of $22,000 \mathrm{mt}$ was maintained. If the 2010 year class turns out to be much smaller than currently estimated (i.e., half the size), a catch equal to the current TAC would still result in an increase in adult biomass in 2013 and 2014 compared to 2011."

Following are corrections to table contents:
Page 48, Table 30. The weights at the beginning of the year for the population for the 2010 year class at ages 2, 3 and 4 were incorrect. Corrected values are indicated in underlined bold red font in the revised Table 30 below.

Page 49, Table 31. The population biomass for the 2010 year class at ages 2, 3 and 4 and the 1+ and 2+ biomass in 2012 and the 1+, 2+ and 3+ biomass in 2013 and 2014 were
incorrect. Corrected values are indicated in underlined bold red font in the revised Table 31 below.

Page 50, Table 32 and 33. The population biomass for the 2010 year class at ages 2, 3 and 4 and the 1+ and 2+ biomass in 2012 and the 1+, 2+ and 3+ biomass in 2013 and 2014 were incorrect. Corrected values are indicated in underlined bold red font in the revised Table 31 below.

Table 30. Input for projections and risk analyses of eastern Georges Bank haddock for the 2011 fishery. A catch of $22,000 \mathrm{mt}$ in 2011 and natural mortality $=0.2$ were assumed for the forecasts. Shaded values indicate the 2003 (yellow), 2005 (grey) and the 2010 (blue) year classes for which year class specific growth patterns were used to determine input values.

Table 32. Bias adjusted deterministic projection results for eastern Georges Bank haddock to beginning of year 2014 for constant quota scenarios of 22, 20, 18, 16 and 14 thousand mt for 2012 and 2013. Partial recruitment to the fishery for the $9+$ group was set at $1 . F$ is for fully recruited ages. Highlighted cells (yellow and green) indicate the 2010 year class at ages 1 to 4 and the 2003 year class at age 8 and in the $9+$ group. Highlighted $F$ values indicate values greater than the $F_{\text {ref }}$. Biomass at the beginning of 2014 is highlighted to facilitate comparison between scenarios.

| Quota | Year | F |  | Age Group |  |  |  |  |  |  |  |  |  |  |

Table 34. Bias adjusted deterministic projection results for eastern Georges Bank haddock to beginning of year 2014 for constant quota scenarios of $22,20,18,16$ and 14 thousand mt . The 2010 year class was reduced to half of its estimated size. Partial recruitment to the fishery for the $9+$ group was set at 1. Highlighted cells (yellow and green) indicate the 2010 year class at ages 1 to 4 and the 2003 year class at age 8 and in the $9+$ group. Highlighted $F$ values indicate values greater than the $F_{\text {ref. }}$. Biomass at the beginning of 2014 is highlighted to facilitate comparison between scenarios.

| Quota | Year | F |  | Age Group |  |  |  |  |  |  |  |  |  |  |

[^0]:    ${ }^{1}$ Based on 2006 to 2010 average except where indicated and ages 5 to $9+$ assumed fully recruited.
    ${ }^{2}$ Based on observed values from 2003 year class.
    ${ }^{3} 2011$ Canadian Department of Fisheries and Oceans (DFO) survey average weights at age except where indicated.
    ${ }^{4}$ Based on a length based growth model (see Table 30). Lengths were converted to weights using a length-weight relationship for commercially caught fish (Waiwood and Nielson 1985) and reduced by $15 \%$ to reflect lower population weights at age (Table 30).
    ${ }^{5}$ The $9+$ group weights are based on the 2003 year class. No growth was assumed for the 2003 year class (in the $9+$ group at age 9, 10 and 11).
    ${ }^{6}$ Based on the 2009 to 2011 age 7 survey average as the 2011 DFO survey value indicated a reduction in weight at age from age 6 to age 7 within the year class (Table 19).
    ${ }^{7} 2010$ Canadian fishery weights at age except where indicated.
    ${ }^{8}$ Based on a length based growth model. Lengths were converted to weights using a length-weight relationship for commercially caught fish (Waiwood and Nielson 1985) (Table 30).
    ${ }^{9}$ Average of 2008 to 2010 Canadian fishery weights at age (rather than using the 2003 year class weight at age 7 which is growing more slowly than other year classes).
    ${ }^{10}$ Average of 2008 to 2010 Canadian fishery weights at age.
    ${ }^{11}$ Average of 2008 to 2010 Canadian fishery weights at age instead of the 2010 age 8 weight which was a drop in weight from age 7 for this year class .
