#### Abstract

The combined 2012 Canada/USA Atlantic Cod catches were 614 mt with a quota of 675 mt , which was the lowest catch since 1978. Catches from the 2013 Fisheries and Oceans Canada (DFO) and National Marine Fisheries Service (NMFS) spring surveys increased from 2012, but all three bottom travel surveys catch were still at lower levels. Both the fishery and the survey catches showed truncated age structure in recent years.

The VPA "M 0.8" model from the 2013 benchmark assessment was used to provide catch advice. In this model, natural mortality ( M ) was assumed to be 0.2 except $\mathrm{M}=0.8$ for ages $6+$ since 1994. A consequence analysis to understand the risks associated with assumptions of the VPA "M 0.8 " and ASAP "M 0.2 " model (with constant M as 0.2 ) was examined in the projection and risk analysis.

While management measures have resulted in a decreased exploitation rate since 1995, total mortality has remained high and adult biomass has fluctuated at a low level. The adult population biomass at the beginning of 2013 was estimated at $11,160 \mathrm{mt}$, which was about $20 \%$ of the adult biomass in 1978. Fishing mortality was high prior to 1994 (0.33-0.66) and was estimated to be 0.07 in 2012. Recruitment at age 1 has been low in recent years. The 2003 year class was estimated to be the highest recruitment since 2000 (excluding the 2010 year class). The initial estimate of the 2010 year class was stronger than the 2003 year class based on the 2013 assessment. Lower weights at age in the population in recent years and poor recruitment have contributed to the lack of rebuilding.

Considering $\mathrm{F}_{\text {ref }}=0.18$ is not consistent with the assessment VPA "M 0.8 " model, it is inappropriate for the catch advice. TRAC recommends basing catch advice on an $F$ lower than $F_{\text {ref }}$ until a different $F_{\text {ref }}$ is negotiated. An $F=0.11$ was used for the catch advice. A $50 \%$ probability of not exceeding an $F=0.11$ implies catches less than $1,225 \mathrm{mt}$. However, given the extremely low SSB and realizing the growth potential from the 2010 year class, catches not exceeding 600 mt would be required in order to not exceed $F=0.11$, and to achieve a $10 \%$ increase in 3+ biomass between 2014 and 2015.

The consequence analysis showed that under both sets of model assumptions, a projected catch of about 600 mt in 2014 would result in low exploitation while achieving a $10 \%$ increase in ages 3+ biomass between 2014 and 2015.

## RÉSUMÉ

En 2012, les prises de morues franches combinées du Canada et des États-Unis se sont chiffrées à 614 tm , sur un quota de 675 tm , le total le plus bas depuis 1978. Les prises des relevés de printemps de 2013 effectués par Pêches et Océans Canada (MPO) et le National Marine Fisheries Service (NMFS) ont augmenté par rapport à 2012, mais les prises des trois relevés au chalut de fond étaient toujours à des niveaux inférieurs. Au cours des dernières années, les prises de la pêche et des relevés ont montré une structure selon l'âge tronquée.

Le modèle d'analyse de population virtuelle (APV) «M=0,8» tiré de l'évaluation de référence de 2013 a été utilisé pour faire des recommandations en matière de prises. Dans ce modèle, la mortalité naturelle $(M)$ est estimée à 0,2 , sauf pour les âges $6+$ où $M=0,8$ depuis 1994. Dans la projection et l'analyse des risques, on a examiné les résultats d'une analyse des conséquences afin de comprendre les risques associés aux hypothèses du modèle d'APV «M=0,8 » et du modèle ASAP «M=0,2 » (avec la constante $M=0,2$ ).

Quoique les mesures de gestion aient eu pour effet de faire baisser le taux d'exploitation depuis 1995, la mortalité totale est demeurée élevée et la biomasse des adultes a fluctué tout en restant faible. La biomasse de la population adulte était estimée à 11160 tm au début de 2013, ce qui correspondait à environ $20 \%$ de la biomasse des adultes de 1978. La mortalité par pêche était élevée avant 1994 (entre 0,33 et 0,66 ) et elle a été estimée à 0,07 en 2012. Le recrutement à l'âge 1 a été faible ces dernières années. On estime que la classe d'âge 2003 représente le plus fort recrutement depuis 2000 (à l'exclusion de la classe d'âge 2010). D'après l'évaluation de 2013, l'estimation initiale de la classe d'âge 2010 était plus élevée que celle de la classe d'âge 2003. Au cours des dernières années, les plus faibles poids selon l'âge au sein de la population, ainsi que le faible recrutement, ont nui au rétablissement du stock.
Comme une mortalité par pêche de référence Fréf de 0,18 ne correspond pas à la valeur calculée à l'aide du modèle d'APV «M=0,8», elle n'est pas appropriée pour les recommandations de prises. Selon le CERT, il faut baser la recommandation de prises sur une mortalité par pêche $F$ inférieure à Fréf jusqu'à ce qu'une autre mortalité par pêche de référence Fréf soit négociée. Une valeur de $F=0,11$ a été utilisée pour les recommandations de prises. Une probabilité de $50 \%$ que la mortalité par pêche ne dépasse pas $\mathrm{F}=0,11$ suppose des prises inférieures à 1225 tm . Cependant, étant donné l'extrême faiblesse de la biomasse du stock reproducteur et le potentiel de croissance de la classe d'âge 2010, les prises devraient être inférieures à 600 tm pour ne pas dépasser $F=0,11$ et parvenir à une augmentation de 10 \% de la biomasse des âges 3+ entre 2014 et 2015.
L'analyse des conséquences a révélé que selon les deux séries d'hypothèses de modèle, des prises prévues d'environ 600 tm en 2014 entraîneraient un faible taux d'exploitation tout en permettant une augmentation de $10 \%$ de la biomasse des âges 3+ de 2014 à 2015.

## INTRODUCTION

The basis and background for the delineation of management units of cod on Georges Bank and the vicinity were reviewed and summarized at the 2009 Eastern Georges Bank cod benchmark assessment meeting (O'Brien and Worcester, 2009). For the purpose of a sharing agreement and consistent management by Canada and the USA, agreement was reached that the transboundary management unit for Atlantic cod would be limited to the eastern portion of Georges Bank (DFO Statistical Unit Areas 5Zej and 5Zem; USA Statistical Areas 551, 552, 561 and 562) (DFO, 2002). The management area is shown in Figure 1. The USA has a requirement for management advice for the Georges Bank cod stock (5Z + SubArea 6). The status quo has been to use an assessment of cod in 5Zjm for transboundary management advice and an assessment of cod in $5 Z+6$ for USA domestic management advice. While other options could be followed, this option is less disruptive to the existing processes. This approach requires concurrent assessment reviews of $5 Z j \mathrm{jm}$ and of $5 Z+6$ to harmonize results.

The model formulations established by the 2009 Eastern Georges Bank cod benchmark assessment (Wang et al., 2009) were used for the eastern Georges Bank cod assessment from 2009 to 2012. In recent assessments the results exhibited persistent strong retrospective pattern. The retrospective analysis showed a tendency to overestimate biomass and underestimate fishing mortality in recent years (Wang and O'Brien, 2012). An Eastern Georges Bank cod benchmark assessment was conducted in 2013 to address these concerns and the details of the model formulation that was agreed upon were documented in the proceedings (Claytor and O'Brien, 2013).

The current assessment applied the 2013 benchmark formulations using Canadian and USA fishery information updated to 2012 including commercial landings and discards, the Fisheries and Oceans Canada (DFO) survey updated to 2013, the National Marine Fisheries Services (NMFS) spring survey updated to 2013 and the NMFS fall survey updated to 2012.

## FISHERY

## COMMERCIAL FISHERY CATCHES

Combined Canada/USA catches averaged 17,198 mt between 1978 and 1993, peaked at $26,463 \mathrm{mt}$ in 1982, and then declined to $1,683 \mathrm{mt}$ in 1995 . They fluctuated around $3,000 \mathrm{mt}$ until 2004 and subsequently declined again. Catches in 2012 were 614 mt , including 128 mt of discards (Table 1, Figure 2). Catches include USA and Canadian discards in all years where discard estimates were available.
Canadian catches peaked at 17,898 mt in 1982 and declined to $1,140 \mathrm{mt}$ in 1995 (Table 1, Figure 3). Since 1995, with lower cod quotas, the fishery has reduced targeting for cod through changes in fishing practices, including the introduction of the cod separator panel for bottom trawls in 1999 (Table 2). From 1995-2011, Canadian catches fluctuated between 743 mt and $3,405 \mathrm{mt}$ (Table 1). In 2012, total catch (extracted landings on May. 26, 2013, 395 mt ) including discards were 468 mt against a quota of 513 mt , taken primarily between July and December by otter trawl and longline (Table 3, Figure 4 and 5). All 2012 landings were subject to dockside monitoring and at sea observers monitored close to $42 \%$ by weight of the mobile gear fleet landings, $26 \%$ by weight of the fixed gear landings and $35 \%$ of the gillnet fleet landings.
Canadian regulations prohibit the discarding of undersized fish from the groundfish fishery. For the Canadian groundfish fishery on eastern Georges Bank during 1978-1996, a review was conducted at the 2013 benchmark meeting to evaluate cod discards (unreported catch). Comparison of length frequencies of observer and port samples did not provide evidence of
discarding. Since there was little quota regulation of the Canadian Georges Bank cod fishery prior to 1995, landings generally were well below the quota, it was concluded that there was no indication of discarding before 1996 (Claytor and O'Brien, 2013). For the Canadian groundfish fishery from 1997 to 2012, the ratio of sums method, which uses the difference in ratio of cod to haddock from observed and unobserved trips, was applied to estimate discards of cod. (Van Eeckhaute and Gavaris, 2004; Gavaris et al., 2006, 2007a)(Table1). In 2007, no discards were attributed to the mobile gear fleet because of the high observer coverage (99\%) and discards for the fixed gear fleet could not be calculated because of the low observer coverage but were assumed to be negligible as discards had not been detected in previous years (Clark et al., 2008). Cod discards from the 2012 Canadian groundfish fishery were estimated at 31 mt from the mobile gear fleet, no discards were detected from the fixed gear fishery (Table 1).

Since 1996, the Canadian scallop fishery has not been permitted to land cod. Landings until 1995 included those catches reported by the scallop fishery. The 3-month moving average observed discards rate has been applied to scallop effort to estimate discards from scallop fishery since 2005 (Gavaris et al., 2007b). Estimated discards of cod by the Canadian scallop fishery ranged between 29 mt to 200 mt annually since 1978 (Van Eeckhaute et al., 2005). In 2012, estimated discards of cod by the Canadian scallop fishery were 42 mt (Table 1).

USA catches increased from 5,502 mt in 1978 to $10,550 \mathrm{mt}$ in 1984. With the implementation of the International boundary (the 'Hague Line') between Canada and the United States in 1984 (International Court of Justice 1984), catches declined and subsequently fluctuated around 6,000 mt between 1985 and 1993 (Table 1, Figure 3). Since December 1994, a year-round closure of Area II (Figure 1) has been in effect, with the exception of less than 3 scallop trips per year in 1999-2000, 2004-2006, 2009, and 2011-2013 and a haddock Special Access Program in 2004 (from August 1st to the following January 31st) and since 2010. Minimum mesh size limits were increased in 1994, 1999 and 2002. Quotas were introduced in May 2004. Limits on sea days, as well as trip limits, have also been implemented (Table 2). With the implementation of a catch share system in 2010, most of the fleets are now managed by quotas. USA catches during 1994-2000 ranged between 544 mt and $1,204 \mathrm{mt}$ and increased to $1,935 \mathrm{mt}$ in 2003, then subsequently declined. Total USA catch (landings and discards combined) was 146 mt for calendar year 2012. The majority of USA landings are usually taken by the second calendar quarter with the least amount landed during the third quarter (Figure 5). Otter trawl gear accounted for $92 \%$ and longline gear about $6 \%$ of the landings, with the remainder taken by gillnet and other unknown gears during 2012.
Discards by USA groundfish fleets occur because of trip limits and minimum size restrictions. In September 2008, the 'Ruhle trawl', which reduces by-catch of cod, was authorized for use on eastern Georges Bank. Cod discarded in the eastern Georges Bank area by otter trawl and scallop fisheries were estimated using the NEFSC Observer data from 1989-2012. A ratio of discarded cod to total kept of all species (d:k) was estimated on a trip basis. Total discards (mt) were estimated from the product of $\mathrm{d}: \mathrm{k}$ and total commercial landings from the Eastern Georges Bank area. In the 2012 SAW55 cod benchmark meeting, 'Delphi' determined mortality rates (otter trawl: 75\%) were applied to the final estimates of USA discards (Table 1). The estimated discards of cod in the groundfish fishery were 55 mt in 2012, a 175\% increase from 20 mt discarded in 2011 (Table 1, Figure 3).

## SIZE AND AGE COMPOSITION

The size and age compositions of the 2012 Canadian groundfish fishery landings were derived from port and at-sea samples from all principal gears and seasons (Table 4, Figure 6). There were representative samples from the mobile gear and fixed gear fishery over all the fishing months. When an observer is on the fishing trip, fish are not discarded. Comparison of port and at-sea length frequencies did not indicate any discrepancies for otter trawlers (Figure 7).

However, fixed gear observer samples had more small fish than the port sample in four of the five months presented (Figure 7). For trips sampled by both port and at sea observers, comparison of length frequencies also indicated some discrepancy (Figure 8). It was suspected that the discrepancies between port and observer samples for fixed gears might be caused by non-randomness of port or observer sampling, or discarding might have occurred although discarding could not be inferred using the ratio of cod to haddock method. At-sea samples were pooled with port samples to derive catch at length and age. Landings peaked at 52 cm (20 in) for bottom trawlers and $70 \mathrm{~cm}(28 \mathrm{in})$ for longliners. Gillnetters caught fewer cod but these fish were larger, peaking at 73 cm ( 29 in ) (Figure 9). The combined landings for all gears peaked at $52 \mathrm{~cm}(20 \mathrm{in})$ (Figure 10). The size composition of cod discards from the 2012 Canadian scallop fishery was derived from at-sea sampling. Cod discards from the scallop fishery peaked at 40 cm (16 in) (Figure 8). The discards from the groundfish fishery were assumed to have the same size composition as the groundfish landings. The Canadian combined cod discards in 2012 from the otter trawl and scallop fisheries peaked at 40 to 55 cm (16 to 22 in ) (Figure 10).

The size and age compositions of the 2012 USA fishery landings on eastern Georges Bank were estimated using port samples of length frequencies and age structures collected from all principal gears and seasons by market category (Table 4). The size and age composition of discarded fish were estimated using at-sea observer samples of length frequency and commercial and NEFSC survey age keys from the same area and season. Landings in 2012 peaked at 56 cm (22 in) and discards peaked at 47 cm (19 in) (Figure 11).

The total catch composition of combined landings and discards for Canada and the USA is shown in Figure 12. Canadian catches peaked at $52 \mathrm{~cm}(20 \mathrm{in})$; and USA catches peaked at 5659 cm (22 to 23 in ).

Otoliths taken from port and at-sea observer samples were used for age determinations. Comparisons have indicated generally good agreement between DFO and NMFS age readers except for two samples with 26 and 41 otoliths, respectively. There was better agreement between DFO inter reader comparisons (Table 5). Further work and detailed discussions on these two samples are needed in the future.

Canadian catch-at-age composition was obtained by applying quarterly fishery age-length keys to the size composition. The age-length key from the 2012 DFO survey was used to augment the first quarter key.
The age composition of the 2012 USA landings was estimated by market category by applying age-length keys to the size composition pooled by calendar quarter, semi-annually, or annually depending on the number of available length samples. The USA sampling protocol is 1 sample per 100 mt of landings (i.e. where 1 length sample=100 fish and 1 age sample=20-25 fish). The 2012 age-length keys were supplemented with age samples from statistical areas 522 and 525 for the catch at age calculations.
Total discards at age from the USA groundfish and scallop fisheries (1989-2012), the Canadian groundfish fishery (1997-2012) and the Canadian scallop fishery (1978-2012) were all included in the assessment.

The 2012 combined Canada/USA fishery age composition, by number, was dominated by the 2009 year class at age 3 (40\%), followed by the 2010 year class at age $2(22 \%)$ and the 2008 year class at age $5(17 \%)$. The 2003 year class at age 9 made little contribution to the 2012 catch (0.3\%) (Table 6, Figure 13). By weight, the 2009 year class dominated the 2012 fishery (30\%) followed by the 2008 (21\%) and 2007 year classes (17\%) (Figure13). The contribution of age 7 and older fish continued to be small in recent years, $3 \%$ by number and $6 \%$ by weight in 2012 (Table 6, Figure 14).

Fishery weights at age showed a declining trend starting in the early 1990s (Table 7, Figure 15). Compared to 2011, the weights at age in 2012 decreased except for ages 1, 4, 5 and 7 and still at low levels.

## ABUNDANCE INDICES

## RESEARCH SURVEYS

Surveys of Georges Bank have been conducted by DFO each year (February/March) since 1986 and by NMFS each fall (October) since 1963 and each spring (April) since 1968. All surveys use a stratified random design (Figures 16 and 17). Most of the DFO surveys have been conducted by the CCGS Alfred Needler. A sister ship, the CCGS Wilfred Templeman, conducted the survey in 1993, 2004, 2007 and 2008 and another vessel, the CCGS Teleost, conducted 6 of the sets in 2006. No conversion factors were applied. For the NMFS surveys, two vessels have been employed and there was a change in the trawl door in 1985. Vessel and door type conversion factors derived experimentally from comparative fishing (Table 8) have been applied to the survey results to make the series consistent (Forrester et al., 1997). Additionally, two different trawl nets have been used on the NMFS spring survey, a modified Yankee 41 from 1973-81 and a Yankee 36 in other years, but no net conversion factors were available for cod. A new net and vessel (FSV Henry B. Bigelow), with revised station protocols have been used to conduct the NMFS spring and fall surveys since 2009. Calibration factors by length were calculated for Atlantic cod for the data collected by the FSV Henry B. Bigelow to make the data equivalent to previous surveys conducted by $F R V$ Albatross IV. The new research vessel/net combination tended to catch more cod at all lengths, but also proportionally more small cod. Length calibration factors (Brooks et al., 2010) were applied to the NMFS spring and fall survey results since 2009 (Table 9).
The spatial distribution of ages 3 and older cod caught during the 2012 NMFS fall, 2013 NMFS spring and 2013 DFO survey were similar to that observed from those surveys over the previous decade, with most fish concentrated on the northeastern part of Georges Bank (Figures 18-20).
The catch in numbers from the 2013 DFO survey was higher than 2012, near the average in the time series (1986-2012) (Table 10). The 2010 year class at age 3 was dominant ( $55 \%$ by number), followed by the 2009 year class at age 4 ( $32 \%$ by number). There was no catch of the 2012 year class at age 1 and no catch of fish older than 8 (Table 10, Figure 21).
Similar to the DFO survey, the 2012 NMFS spring survey catch increased from 2012 and was above the average of the 1978-2012 time series (Table 11). One large tow from stratum 21 accounted for $66 \%$ of the total catch. The 2010 year class at age 3 was dominant ( $65 \%$ by number), followed by the 2009 year class at age 4 ( $20 \%$ in number). There were no fish caught from the 2012 year class at age 1 and no catches of fish older than age 7 (Table 11, Figure 21).
The catch from the NMFS 2012 fall was among the lowest since 1978. The 2010 year class at age 2 was dominant ( $58 \%$ by number), followed by the 2009 year class at age 3 ( $28 \%$ by number). There were no catches of fish older than age 5 (Table 12).
The coefficient of variation (CV) of stratified mean catch number/tow for the three surveys is shown in Tables 13-15 and Figure 22. Median CV values indicated the most variable catch for ages 1 and 8 for DFO and NMFS spring surveys as well as ages 1 and 5 for the NMFS fall survey. The CVs were similar between the DFO and NMFS spring surveys and smaller compared to the NMFS fall survey values. The catch from all three surveys became more variable after mid-1990s, which might be caused by patchy distribution at low abundance.
With the exception of the 1996, 1998, 2003, and 2006 year classes and potentially the 2010 year class (all of which were below the time series average), the survey abundance at age
(Tables 10-12, Figure 21) shows poor recruitment since the 1990 year class in all three surveys. The 2003 year class has appeared strong in the DFO and spring surveys until age 7 and in the fall surveys until age 3, however they were disappearing very fast after age 9 from DFO survey and from age 8 from NMFS spring survey. The 2010 year class was prominent in all three surveys. Compared with pre-1990 surveys, representation at older ages and younger ages in recent years continues to be poor (Figure 21).

Biomass indices at age were calculated by applying weight at age to the abundance indices at age. The survey biomass in the 2012 fall survey was lower than last year. DFO survey biomass has been fluctuating with no strong trend. NMFS spring and fall surveys biomass indices have been low since the mid-1990s (Figure 23).

The average weights at age derived from the DFO survey and NMFS spring survey were used to represent the population weight at age for the beginning of the year. All the weights at age display a declining trend since the early 1990s (Table 16, Figure 24). Weights at age in 2013 are lower than in 2012 except for ages 2 and 3.

Fulton's condition factor (K), an indicator which uses observed weight and length to measure fish condition, was calculated using the data from all three surveys. In order to reduce the impact of gonad weight, the post-spawning fish samples were used for the Fulton's K calculation. It showed notable downward trends in recent years from DFO and NMFS spring samples. There were limited catches from the NMFS fall survey (Table 17), and the trend from those samples was not clear (Figure 25).

## HARVEST STRATEGY

The Transboundary Management Guidance Committee (TMGC) has adopted a strategy to maintain a low to neutral risk of exceeding the fishing mortality reference. At the 2013 benchmark meeting, it was agreed that the current $\mathrm{F}_{\text {ref }}=0.18$ (TMGC meeting in December, 2002) is not consistent with the VPA "M 0.8 " model, and a lower value for $\mathrm{F}_{\text {ref }}$ would be more appropriate (Claytor and O'Brien, 2013). When stock conditions are poor, fishing mortality rates should be further reduced to promote rebuilding.

## ESTIMATION AND DIAGNOSTICS

## CALIBRATION OF VIRTURAL POPULATION ANALYSIS (VPA)

At the benchmark assessment review in 2013, there was no consensus on a benchmark model, however, the TRAC did agree to provide catch advice based on a virtual population analysis (VPA) model (Claytor and O'Brien, 2013). The VPA used fishery catch statistics and size and age composition of the catch from 1978 to 2012 (including discards). The adaptive framework, ADAPT (Gavaris 1988), was used for calibrating the VPA with trends in abundance from three research bottom trawl survey series: NMFS spring, NMFS fall and DFO. Computational formulae used in ADAPT are described by Rivard and Gavaris (2003a).
In this model, natural mortality (M) was assumed equal to 0.2 except for ages 6+ from 1994 onwards where M was fixed at 0.8 . The data used in the model were:
$C_{a, t}=$ catch at age for ages $\mathrm{a}=1$ to $10+$ and time $t=1978$ to 2012, where t represents the year during which the catch was taken
$I_{1, \mathrm{a}, \mathrm{t}}=$ DFO survey for ages $\mathrm{a}=1$ to 8 and time $\mathrm{t}=1986.17,1987.17 \ldots 2012.17,2013.00$
$I_{2, a, t}=$ NMFS spring survey (Yankee 41) for ages $a=1$ to 8 and time $t=1978.28,1979.28$, 1980.28, 1981.28
$I_{3,, a, t}=$ NMFS spring survey (Yankee 36), for ages $a=1$ to 8 and time $t=1982.28,1983.28 \ldots$ 2012.28, 2013.00
$I_{4, \mathrm{a}, \mathrm{t}}=$ NMFS fall survey, ages $a=1$ to 5 and time $t=1978.69,1979.69 \ldots 2011.69,2012.69$
The population was calculated to the beginning of 2013; therefore the DFO and NMFS spring survey indices for 2013 were designated as occurring at the beginning of the year, i.e. 2013.00. The benchmark formulations assumed that observation errors for the catch at age data were negligible. Observation errors for the abundance indices at age were assumed to be independent and identically distributed after taking natural logarithms of the values. Zero observations for abundance indices were treated as missing data as the logarithm of zero is not defined. Fishing mortality on age 9 for 1978 to 2012 was assumed to be equal to the population weighted average fishing mortality on ages 7 and 8 .

Estimation was based on minimization of the objective function:
$\sum_{s, a, t}\left(\ln I_{s, a, t}-\left(\hat{\kappa}_{s, a}+v_{a, t}\right)\right)^{2}$, where $s$ indexes survey.
The estimated model parameters were:
$v_{\mathrm{a}, \mathrm{t}}=\ln N_{\mathrm{a}, \mathrm{t}}=\ln$ population abundance for $\mathrm{a}=2$ to 9 at beginning of 2013
$K_{1, \mathrm{a}}=\ln$ DFO survey catchability for ages $\mathrm{a}=1$ to 8 at time $t=1986$ to 2013
$K_{2, a}=\ln$ NMFS spring survey (Yankee 41) catchability for ages $a=1$ to 8 at time $t=1978$ to 1981
$K_{3, a}=\ln$ NMFS spring survey (Yankee 36) catchability for ages $\mathrm{a}=1$ to 8 at time $t=1982$ to 2013
$K_{4, a}=\ln$ NMFS fall survey catchability for ages $a=1$ to 5 at time $t=1978$ to 2012
Statistical properties of the estimators were determined using conditional non-parametric bootstrapping of model residuals (Efron and Tibshirani, 1993; Rivard and Gavaris, 2003a).

The population abundance estimate of the 2011 and 2010 year classes at age 2 and 3 at beginning of 2013 exhibited the largest relative bias of $11 \%$ and $9 \%$, respectively. The relative bias for other ages ranged between 3\% and 5\%. The relative error ranged between $59 \%$ and 25\% (Table 18). Survey catchability ( $q$ ) at age progressively increased until age 5 for DFO and NMFS spring surveys (Figure 26). Survey catchability at age for the NMFS fall survey was very low (Figure 26).

The overall fit of model estimated biomass to the DFO, NMFS spring and NMFS fall surveys was generally consistent with the survey trends after 1994 (Figure 27). There were residual patterns which suggested obvious year effects (Figure 28). Average fishing mortality (F4-9) by time blocks for 1978-1993, 1994-2007 and the recent 5 years (2008-2012) was 0.49, 0.27 and 0.15 , respectively. The temporal trend of fishing mortality was consistent with fishery management effort trend. There was relatively flat fishery partial recruitment pattern except for the 10+ group (Figure 29).

Retrospective analysis was used to detect any bias of consistently overestimating or underestimating fishing mortality, biomass and recruitment relative to the terminal year estimates. With catch data through 2011, the VPA "M 0.8 " model did not show any retrospective pattern, suggesting that model assumptions on natural mortality are appropriate and that the fishery catch at age is consistent with the survey indices. However, in the assessment with catch data through 2012, the 2003 year class was estimated to be substantially smaller than the estimate from the 2013 benchmark model formulation with one less year of data. It was estimated at 4.1 million at age 1 in the 2013 assessment compared with 13.5 million with one
less year of data (Figures 30 and 31). Residuals from the VPA predicted survey values for each of the three surveys were predominantly positive, which means that the 2003 year class was underestimated in the 2013 assessment (Figure 32).

Possible reasons for the appearance of a retrospective bias after adding one more year of data were explored. At the benchmark model review, with catch data through 2011 as described above, the age 9 in 2012 (2003 year class) was estimated directly as a model parameter. Since only ages 1-8 from the DFO and NMFS spring surveys and ages 1-5 from the fall survey are used to calibrate the catch-at-age matrix, the determination of the 2003 year class in the 2013 assessment relied on the 2012 fishery age 9 (2003 year class) catch and the assumption that F9 is equal to the population weighted average $F$ on ages 7 and 8 of adjacent year classes.

The prevalence of age 9 fish in the 2012 fishery catch was expected to be high based on the abundance of the 2003 cohort in each of the previous age classes. However, a proportionately low value of age 9 catch accounted for only $0.3 \%$ in number in the 2012 fishery catch, which led to a much lower estimate of this cohort and contributed to a retrospective bias.

Another possible reason for the retrospective bias is if the actual M experienced by the 2003 year class between ages 8 and 9 was higher than that assumed ( 0.8 ). Using the assumed M would artificially reduce the abundance of the entire 2003 cohort in the backward calculation (even if the 0.8 is a good approximation of M among ages 6,7 and 8 ). Sensitivity runs were conducted to explore the uncertainties in estimation of the 2003 year class. The impact on the estimate of terminal year (2013) population abundance of other year classes, the retrospective pattern, as well as the implication for the projection were also investigated.

## Sensitivity Analyses

In the following sensitivity runs, the model set up was the same as the VPA "M 0.8 " model formulation described above for the 2013 assessment except for:

- Run 1: Estimating the 2003 year class at age 9 ('estimate 2003yc' model). In this model, the abundance of the 2003 year class at age 9 in 2012 was estimated as a parameter. Thus, neither age 9 fishery catch nor the assumption on F at age 9 as an average of adjacent year classes was used in the estimation of the age 9 population number of the 2003 year class.
- Run 2: Removing the 2003 year class survey data entirely from the data input ('without 2003yc' model). In this sensitivity run, the abundance of the 2003 year class at age 1 was fixed at a value of 4.1 million, which is the same value as 2013 assessment output from the "M 0.8 " model . Since no 2003 year class survey data were used in the calibration and objective function, this fixed value has no impact on other year class estimations.
The estimated 2003 year class numbers at age from run 1 were compared with the 2012 and 2013 assessments. The 2003 year class from the "estimate 2003yc" model was very close to the 2012 assessment, about 13.5 million fish at age 1, well above 4.1 million age 1 fish from the 2013 assessment (Figure 33). Also, the estimate of biomass and fishing mortality of 1978-2012 from run 1 were much closer to the 2012 assessment (Figure 30).
For both run 1 and run 2, the estimated terminal year population abundance at age was compared with the 2013 assessment and the estimated recruitments for the past years were compared with the 2012 and 2013 assessment. For the terminal year 2013 population numbers at age, there were very minor differences between the three model formulations for most of the ages except for the 2010 year class at age 3 and age 10+ (Table 19 and Figure 34). The 2013 assessment with "M 0.8 " model estimated the 2010 year class at 4.2 million compared with about 4.4 and 4.9 million from the 2 sensitivity runs (Table 19).

The "estimate 2003 yc" model has the highest estimation of ages 10+ at 168,000 with deeply dome shaped PR compared with 19,000 from the 2013 assessment using VPA "M 0.8" model.

However, the difference in the terminal year ages 3-9 biomass is minor between the three model formulations (Table 19 and Figure 35). Although the 2013 assessment tended to underestimate the size of pre-2003 year classes, the estimated recruitment for the most recent 5 years was very similar among all models (Table 19 and Figure 36). The 2003 year class was underestimated in the 2013 assessment relative to the other model formulations (Table 19 and Figure 36).

## STATE OF RESOURCE

The above sensitivity analyses suggest that the low estimate of the 2003 year class may be an outlier which then caused a retrospective bias in the 2013 assessment. However, it had little impact on the estimation of other year classes in the terminal year or recruitments in the most recent five years. The adult biomass, recruitment, and fishing mortality estimates (Tables 20-22) presented below were from the VPA "M 0.8 " model.

Adult population biomass (ages 3+) declined substantially from about 52,000 mt in 1990 to below 16,000 mt in 1995, the lowest observed at that time (Table 20, Figure 37). Biomass has subsequently fluctuated between $5,800 \mathrm{mt}$ and $18,800 \mathrm{mt}$. The estimate of $3+$ biomass was $11,160 \mathrm{mt}$ ( $80 \%$ confidence interval: $9,161 \mathrm{mt}-14,550 \mathrm{mt}$ ) at the beginning of 2013 (Table 20). The increase of 3+ biomass during 2005-2009 was largely due to the recruitment and growth of the 2003 year class (Figure 37). The increase in biomass since 2011 is largely due to the recruitment and growth of the 2010 year class. High natural mortality, lower weights at age in the population in recent years, and generally poor recruitment have contributed to the lack of sustained rebuilding. Survey biomass indices have been lower since the mid-1990s (Figure 23). The estimated adult population biomass at the beginning of 2013 from the VPA was about one fifth of the 1978 biomass (Figure 37).
Recruitment at age 1 has been low in recent years (Table 21, Figure 37). Since 2000, the 2003 year class at 4.1 million fish at age 1 ( 13.5 million fish at age 1 from the 2012 assessment), had been the highest recruitment estimated. However, the initial estimate of the 2010 year class at 6.4 million age 1 fish is stronger than the 2003 year class based on the 2013 assessment. The uncertainty in the 2010 year class estimate is high, with a $40 \%$ relative standard error on age 3. Both the 2003 and 2010 year classes are around half of the average (about 11 million age 1 fish) during 1978-1990, when the productivity was considered to be higher (Table 21, Figure 37). Recruitment for the 2002 and 2008 year classes are the lowest on record. The current biomass is well below $25,000 \mathrm{mt}$, above which there is expected to be a better chance for higher recruitment (Figure 38). Recruitment indices from the research bottom trawl surveys for the 2012 year class could not be estimated; there were no fish of this year class caught in any of the three surveys.
Fishing mortality (population number weighted average of ages 4-9) was high prior to 1994 (Table 22, Figure 39). F declined in 1995 to $\mathrm{F}=0.11$ due to restrictive management measures and then fluctuated between 0.07 and 0.38 . F in 2012 was estimated to be 0.07 ( $80 \%$ confidence interval: 0.06-0.09). The assessment showed recent reductions in F, and the 2012 fishing mortality was below $F_{\text {ref }}=0.18$. However, because the current $F_{\text {ref }}$ was based on an assumption of $\mathrm{M}=0.2$, the value is not appropriate for comparison with the VPA "M 0.8 " model results (Claytor and O'Brien, 2013).
Yield exceeded surplus production during the early 1990s (Figure 40). Surplus production since the mid-1990s has remained considerably lower than that prior to 1990. Growth of ages 2 to 10 has typically accounted for the greatest percentage of the production. Occasionally, a strong incoming year-class at age 2 makes a greater contribution to production. The 2003 year class made such a contribution in 2005. In 2009 and 2010, yield exceeded surplus production (Figure 41).

## PRODUCTIVITY

Recruitment, age structure, fish growth and spatial distribution typically reflect changes in the productive potential. While management measures have resulted in a decreased exploitation rate since 1995, total mortality has remained high and adult biomass has fluctuated at a low level. The current biomass is well below 25,000 mt; when biomass is above this threshold, there is a better chance for higher recruitment (Figure 38). Average weight at length, used to reflect condition, has been stable in the past, but has started to decline in recent years. Size at age in the 2012 fishery remains low (Table 16). The research survey spatial distribution patterns of adult (age 3+) cod have not changed over the past decade (Figures 19-21). Lower weights at age in the population in recent years and poor recruitment have contributed to the lack of rebuilding.

## OUTLOOK

This outlook is provided in terms of consequences with respect to the harvest reference points for alternative catch quotas in 2014 (Gavaris and Sinclair, 1998; Rivard and Gavaris, 2003b). At the 2013 cod benchmark meeting (Claytor and O'Brien, 2013), it was agreed that the current $F_{\text {ref }}=0.18$ is not consistent with the VPA "M 0.8 " model given that it was derived based on models with an $M=0.2$. Although no consensus was reached as to what an appropriate $F_{\text {ref }}$ would be for the VPA "M 0.8 " model, it was agreed that it should be lower. The TRAC agreed that projections would be run at the current $F_{\text {ref }}$ of 0.18 and at a value less than the $F_{\text {ref }}$, and the assessment leads should pick the most meaningful values for the projection. Therefore a value of $F=0.11$ was used to provide catch advice for 2014. This value was derived from an agedisaggregated Sissenwine-Shepherd production model using $M=0.8$ that was presented at the April 2013 benchmark (Claytor and O'Brien, 2013). Although it was not accepted as $\mathrm{F}_{\text {ref }}$ value for the "M 0.8 " model at the benchmark, the value of $F=0.11$ was used for the second projection analysis at the 2013 TRAC since it was below 0.18 and therefore in keeping with the advice.
Uncertainty about current biomass generates uncertainty in forecast results, which is expressed here as the probability of exceeding $F_{\text {ref }}=0.18$ or $F=0.11$ and as the change in adult biomass from 2014 to 2015. The risk calculations assist in evaluating the consequences of alternative catch quotas by providing a general measure of the uncertainties. However, risk calculations are dependent on the data and model assumptions and do not include uncertainty due to variations in weight at age, partial recruitment to the fishery, natural mortality, systematic errors in data reporting, the possibility that the model may not reflect stock dynamics closely enough, and retrospective bias.
For projections, the average of the most recent three years of fishery and survey weights at age was used for fishery and beginning year population biomass for 2014 and 2015. The 2013 and 2014 partial recruitment pattern was based on the most recent five years of estimated partial recruitment (Table 23). The 2008-2012 geometric mean of recruitment at age 1 was used for 2013-2015 projections. The initial indication of the 2012 year class is very weak, thus the projection could be optimistic. Catch in 2013 was assumed to be equal to the 600 mt quota, and $\mathrm{F}=0.18$ or $\mathrm{F}=0.11$ in 2014.

## PROJECTION BASED ON FREF=0.18

Table 24 shows the deterministic projection results, where the projected catch at $\mathrm{F}_{\text {ref }}=0.18$ would be $2,028 \mathrm{mt}$ in 2014. Because $\mathrm{F}_{\text {ref }}=0.18$ is not consistent with the " M 0.8 " assessment model, it is inappropriate for catch advice. The stochastic projection indicates catch at $\mathrm{F}_{\text {ref }}=0.18$ will not achieve a 10\% increase in adult biomass (3+) in 2015 (Table 25, Figure 42).

## PROJECTION BASED ON F=0.11

Both deterministic (Table 26) and stochastic (Table 25, Figure 42) projections based on F=0.11 are provided. A $50 \%$ probability of not exceeding $F=0.11$ implies a combined Canada/USA catch less than 1,225 mt (Table 25, Figure 42). Catches of 2,075 mt will result in a neutral risk (50\%) that the 2015 adult biomass will be lower than 2014, a catch of 600 mt will result in a neutral risk (50\%) that 2014 adult biomass will not increase by 10\% (Figure 42).

## SENSITIVITY ANALYSIS

To examine the effect of the uncertainties in the estimation of the 2003 year class, the "estimate 2003yc" model was used as a sensitivity analysis for projections. The strong dome-shaped partial recruitment for ages 10+ from the model results was applied in the projection (Table 23). Deterministic (Table 26) and stochastic (Table 25, Figure 43) projections are provided. Catches of 750 mt will result in a neutral risk (50\%) that the 2015 adult biomass will be lower than 2014, a catch of 650 mt will result in a neutral risk (50\%) that 2014 adult biomass will not increase by 10\% (Figure 43).

Given the extremely low biomass, management should try to realize the growth potential from the 2010 year class to rebuild the spawning stock biomass. In order to not exceed $F=0.11$, and to achieve a $10 \%$ increase in biomass, catches must not exceed 600 mt (Table 25, Figure 42). No fishing in 2014 implies an increase in adult biomass from 2014 to 2015 of about 15\%.

## CONSEQUENCE ANALYSIS

The risks associated with management actions taken during 2014 were examined with a consequence analysis by undertaking stock projections under the competing assumptions of the 'state of nature'. The two states of nature are the VPA "M 0.8" model and the ASAP M 0.2 model, both presented at the 2013 cod benchmark model meeting (Claytor and O'Brien, 2013) and updated through 2012 in this assessment and reviewed at the June 2013 TRAC. At the benchmark model meeting, the TRAC agreed to apply the VPA "M 0.8" model for providing catch advice, however, given that $\mathrm{F}_{\text {ref }}=0.18$ is no longer consistent with that model, the TRAC also agreed to provide a consequence analysis of projected catch at two different fishing mortality rates from both models.
The analysis presents the consequences of management actions taken by setting projected catch according to the VPA "M 0.8 " model if the true state of nature is such that M has remained unchanged at 0.2 and stock productivity is best reflected by the ASAP M 0.2 model, and conversely, if management actions were taken by setting projected catch according to the ASAP M 0.2 model (Appendix $A$ ) while the true state of nature is such that M has increased to 0.8 and stock productivity is best reflected by the VPA "M 0.8 " model.

Data input to each model projection is as previously described for the VPA "M 0.8 " and for ASAP M 0.2 (Appendix A). These are short term projections, for one year to 2014, and do not account for any longer-term consequences.

The column headers in Table 27 represent the 'true' states of nature:

- VPA M $0.8 \mathrm{M}=0.2$ except $\mathrm{M}=0.8$ for ages $6+$ from 1994 onward
- ASAP $0.2 \mathrm{M}=0.2$ for all ages and all years

The row headers indicate the basis of the management action during the projected period (2014) for four different catches. The notation in parentheses indicates where that catch was derived, e.g., the row with a $1,225 \mathrm{mt}$ catch was projected from the VPA "M 0.8 " model at $\mathrm{F}=0.11$.

The cells of the table indicate the projected 2014 fully recruited F and 2015 January 1 ages 3+ biomass, and the projected percent increase in biomass from 2014 to 2015.

If the VPA "M 0.8 " model assumptions are the 'true state of nature', fishing at projected catch of $2,028 \mathrm{mt}$ at $\mathrm{F}_{\text {ref }}=0.18$ would not allow for a biomass increase in 2015. A 10\% increase in 2015 biomass is only expected fishing at an $\mathrm{F}=0.05$ and a catch of 601 mt . If the ASAP $\mathrm{M}=0.2$ model assumptions are the 'true state of nature', implementing the VPA 0.8 projected catch for $\mathrm{F}_{\text {ref }}$ results in $\mathrm{F}=0.75$ and loss of 2015 biomass of about 20\%. Fishing at ASAP projected catch of 601 mt at $\mathrm{F}_{\text {ref }}=0.18$ results in projected biomass increase of $10 \%$.

In summary, based on both model projections, 2014 catches at about 600 mt would allow for low exploitation of the stock and at least a minimum 10\% increase in the 2015 projected biomass can likely be attained. A catch of 600 mt would be similar to the recent negotiated quota for fishing years 2012 and 2013.

The consequence analysis reflects the uncertainties in the assessment model assumptions. Despite these uncertainties, all assessment results indicate that low catches are needed to promote rebuilding.

## SPECIAL CONSIDERATIONS

Table 28 summarizes the performance of the management system. It reports the TRAC advice, TMGC quota decision, actual catch, and realized stock conditions for this stock. Fishing mortality and trajectory of age 3+ biomass from the assessment following the catch year are compared to results from this assessment. These comparisons were kindly provided in 2011 by Tom Nies (staff member of the New England Fishery Management Council (NEFMC)) and updated for this assessment. The management advice and performance since 1999 are summarized in Table 28, which was kindly provided by Tom Nies (staff member of the New England Fishery Management Council, NEFMC). The TRAC advice, TMGC quota decision, actual catch, and realized stock conditions for eastern Georges Bank cod are compared. The inconsistency of TRAC advice in the past with the realized stock conditions from the recent assessment was mainly due to the assessment model changes after the 2009 benchmark assessment, and the retrospective bias in the assessment also accounted for part of this inconsistency.
Cod and haddock are often caught together in groundfish fisheries, although they are not necessarily caught in proportion to their relative abundance because their catchabilities to the fisheries differ. Due to the higher haddock quota, discarding of cod may be high and should be monitored; at-sea observers are an essential component of this monitoring. Modifications to fishing gear and practices, with enhanced monitoring, may mitigate these concerns.
In July 2013, there will be a reduction in the minimum size for the US fishery from 22 inches to 19 inches. This is expected to result in reduced discards and a possible change in PR for the youngest ages.

It was agreed at the 2013 TRAC that projections would be run at the current Fref of 0.18 and at a value less than 0.18 . A value of $\mathrm{F}=0.11$ was used to provide catch advice for 2014. A consequence analysis was used to determine risks under alternative model assumptions. Further investigation will be required to determine an appropriate recommendation for an exploitation rate for the benchmark model.

## ACKNOWLEDGEMENTS

We thank L. Van Eechaute for providing the Canadian discards data, L. Brown of DFO and N . Shepherd for providing ageing information for the DFO and NMFS surveys and Canadian
and USA fisheries., G. Donaldson and D. Frotten of DFO and at sea observers from Javitech Ltd. for providing samples from the Canadian fishery.

Table 2. Canadian and USA fishery management history of cod on eastern Georges Bank, 1978-2011.

| 2a. Canadian Management History |  |
| :---: | :---: |
| 1978 | Foreign fleets were excluded from the 200 mile exclusive economic zones of Canada and USA; |
| 1984 | Oct. Implementation of the maritime boundary between the USA and Canada in the Gulf of Maine Area; |
| 1985 | $5 Z$ cod assessment started in Canada Set TAC; TAC=25,000 mt |
| 1986 | TAC=11,000 mt |
| 1987 | TAC $=12,500 \mathrm{mt}$ |
| 1988 | TAC $=12,500 \mathrm{mt}$ |
| 1989 | TAC $=8,000 \mathrm{mt}$ 5Zjm cod assessment |
| 1990 | Changes to larger and square mesh size; Changes from TAC to individual and equal boat quotas of 280,000 lbs with bycatch restrictions; Temporary Vessel Replacement Program was introduced. |
| 1991 | TAC $=15,000 \mathrm{mt}$ Dockside monitoring Maximum individual quota holdings increased to $2 \%$ or $600 t$ (whichever was less). |
| 1992 | TAC=15,000 mt <br> Introduction of ITQs for the OTB fleet |
| 1993 | TAC $=15,000 \mathrm{mt}$, ITQ for the OTB fleet not based on recommended catch quotas; OTB < 65 fleet was allowed to fish during the spawning season (March-May. 31). |
| 1994 | TAC=6,000 mt, <br> Spawning closures January to May $31^{\text {st }}$; <br> Mesh size was 130 mm square for cod, haddock and pollock for ITQ fleet; Minimum mesh size of 6 " was required for gillnets; <br> Minimum fish size is 43 cm (small fish protocols) for cod, haddock and pollock for ITQ fleet; OT> 65' could not begin fishing until July $1^{\text {st; }}$; <br> Fixed gear must choose to fish either $5 Z$ or $4 X$ during June $1^{\text {st }}$ to September $30^{\text {th }}$. |
| 1995 | TAC $=1,000 \mathrm{mt}$ as a bycatch fishery; <br> January $1^{\text {st }}$ to June $18^{\text {th }}$ was closed to all groundfish fishery; <br> 130 mm square mesh size for all mobile fleets; <br> Small fish protocols continued; <br> $100 \%$ dock side monitoring; <br> Fixed gear vessels with a history since 1990 of 25 t or more for 3 years of cod, haddock, pollock, hake or cusk combined can participate in $5 Z$ fishery. |
| 1996 | TAC=2,000 mt; <br> Prohibition of the landing of groundfish (except monkfish) by the scallop fishery; <br> ITQ vessel require minimum 130 mm square mesh for directed cod, haddock and pollock trips; <br> Small fish protocols continued; <br> For community management, quota allocation of each fixed gear based on catch history using the years 1986-1993; <br> $100 \%$ mandatory dockside monitoring and weighout. |
| 1997 | TAC=3,000 mt |
| 1998 | TAC=1,900 mt |
| 1999 | TAC=1,800 mt; Mandatory cod separator panel when no observer on board; January and Februay mobile gear winter pollock fishery. |
| 2000 | $\begin{aligned} & \text { TAC }=1,600 \mathrm{mt} \\ & \text { January and February mobile gear winter pollock fishery } \end{aligned}$ |
| 2001 | TAC=2,100 mt |
| 2002 | TAC=1,192 mt |
| 2003 | TAC=1,301 mt; |
| 2004 | TAC=1,000 mt; Canada-USA resource sharing agreement on Georges Bank. |

| 2a. Canadian Management History |  |
| :---: | :---: |
| 2005 | TAC=740 mt; Exploratory winter fishery January to February 18, 2005; Spawning protocol: 25\% of maturity stages at 5 and 6 . |
| 2006 | TAC=1,326 mt; Exploratory winter fishery January to February.6, 2006; Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2007 | TAC=1,406 mt; <br> Exploratory winter fishery January to February 15, 2007; High mobile gear observer coverage (99\%); Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2008 | TAC=1,633 mt; <br> Winter fishery from January $1^{\text {st }}$ to February 8, 2009; <br> At-sea observer coverage $38 \%$ by weight of the mobile gear fleet landings and $21 \%$ by weight of the fixed gear landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2009 | TAC=1,173 mt; <br> Winter fishery from Jan.uary $1^{\text {st }}$ to February 21, 2009; <br> At-sea observer coverage $23 \%$ by weight of the mobile gear fleet landings and $15 \%$ by weight of the fixed gear landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2010 | TAC=1,350 mt; <br> Winter fishery from January $1^{\text {st }}$ to February 8, 2010; <br> At- sea observer coverage $18 \%$ by weight of the mobile gear fleet landings and $6 \%$ by weight of the fixed gear landings; <br> Spawning protocol: 30\% of maturity stages at 5 to 7 . |
| 2011 | TAC=1,050 mt; <br> Winter fishery from January $1^{\text {st }}$ to February 5, 2011; <br> At- sea observer coverage $19 \%$ by weight of the mobile gear fleet landings, $20 \%$ by weight of the fixed gear landings and $3 \%$ by weight of the gillnet fleet landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2012 | TAC=513 mt; <br> Winter fishery from January $1^{\text {st }}$ to February 6, 2012; <br> At-sea observer coverage $42 \%$ by weight of the mobile gear fleet landings, $26 \%$ by weight of the fixed gear landings and $35 \%$ by weight of the gillnet fleet landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |

## 2b. USA Management History

| Year | Regulatory Actions |
| :---: | :---: |
| 1953 | ICNAF era |
| 1973-1986 | TAC implemented for Div 5Zcod; 35,000/year |
| 1977 | Groundfish Fishery Management Plan (FMP) Magnuson-Stevesn Conservation Management Act (MSCMA) |
| 1982 | Interim FMP |
| 1984 | Hague Line implemented |
| 1985 | Multi-species FMP |
| 1989 | Amendment 2 |
| 1994 | Emergency Rule - December Year round closures in effect |
| 1994 | Amendment 5; Days at Sea (DAS) monitoring ; Mandatory reporting : Vessel Trip Reports (VTR) |
|  | Amendment 6 |
| 1996 | Amendment 7; accelerated DAS reduction |
|  | Sustainable Fisheries Act (SFA) |
| 1999 | Amendment 9 |
| 2002 | Interim rule; 20 \% reduction in DAS |
| 2004 | Amendment 13; further reduction in DAS; hard TAC on EGB haddock and cod |
|  | Eastern US/CA Area haddock Special Access Program (SAP) Pilot Progam |
| 2005 | DAS vessels limited to one trip/month in Eastern US/CA Area until April 30; |
|  | Limited accesss DAS vessels required to use separator panel trawl in the area |
| 2006 | Haddock separator trawl or flounder net required in Eastern US/CA area |
| 2008 | Eastern US/CA Area access delayed until Aug 1, except longline gear |
|  | Sept - Ruhle trawl (eliminator trawl) allowed in Eastern US/CA area |
| 2009 | Nov- Eastern US/CA area , trawl vessels requried to use separator/Ruhle south 41-40N |
| 2010 | Amendment 16, Framwork 44 implemented; Sector management ; Prohibition on discarding legal size fish |
|  | US/CA area:prohibition on discarding legal size fish |
|  | Mesh Sizes (inches) |
| 1953 | 4.5 |
| 1977 | 5.125 |
| 1983 | 5.5 |
| 1987 | 6.0 |
| 1989 | eliminate 6 inch increase |
| 1994 | 6.0 |
| 1999 | 6.5 square mesh/ 6.0 diamond mesh |
| 2000 | 6.5 square mesh/ 6.5 diamond mesh |
| 2002 | 6.5 square mesh/ 6.5 diamond mesh/6.5 gill net |
|  | Minimum Size |
| 1977 | 16 inches( 40.6 cm ) commercial and recreational |
| 1982 | 17 inches (43.2 cm) commercial; 15 inches ( 38.1 cm ) recreational |
| 1986 | 19 inches ( 48.3 cm ) commercial; 17 inches ( 43.2 cm ) recreational |
| 1988 | 19 inches ( 48.3 cm ) commecial and recreational |
| 1997 | 21 inches (53.3) recreational |
| 2002 | 22 inches ( 55.9 cm ) commercial; 23 inches ( 58.4 cm ) recreational |
| 2003 | 21 inches ( 53.3 cm ) recreational |
| 2013 | 19 inches ( 48.3 cm ) commercial |

| Year | Trip Limits |
| :---: | :---: |
| 2004 | GB cod: 1,000 lbs/day; 10,000 lbs/trip; EGB: hard TAC on cod |
|  | $500 \mathrm{lbs} / \mathrm{day}$; 5,000 lbs/trip in Eastern US/CA area |
| 2005 | $500 \mathrm{lbs} / \mathrm{day}$; 5,000 lbs/trip in Eastern US/CA area |
|  | Starting July, one trip/month in Eastern US/CA area until Apr. 30, 2006 |
| 2006 | $500 \mathrm{lbs} / \mathrm{day}$; 5,000 lbs/trip in Eastern US/CA area |
| 2007 | $1000 \mathrm{lbs} /$ trip of cod in Eastern US/ CA area or Haddock SAP |
| 2008 | $1000 \mathrm{lbs} /$ trip of cod in Eastern US/ CA area fishing EGB exlclusively |
| 2009 | Mar-500 lbs/ trip of cod in Eastern US/CA area; back to 1000 in April |
|  | Apr 16 - Eastern US/CA area closed until May 1 |
| 2010 | GB Cod: $2000 \mathrm{lbs} /$ day; 20000/trip ; EGB cod: $500 \mathrm{lbs} /$ day, $5000 \mathrm{lbs} / \mathrm{trip}$ |
| 2011 | March- 3,000 lbs day during April |
|  | $500 \mathrm{lbs} /$ day after April in EGB area |
|  | Closures |
| 1970 | Area 1(A) and 2 (B) Mar-Apr |
| 1972-1974 | Area 1(A) and 2 (B) Mar-May |
| 1977 | seasonal spawning closure |
| 1987 | modify closed area I to overlap with haddock spawning area |
| 1994 | Jan. CA Il expanded, closed Jan-May, CA I closed to all vessels except sink gillnet |
|  | Dec. CA I and II closed year round to all vessels |
| 1999 | scallopers allowed limited access to CA II |
| 2004 | May to Dec. access to northern corner of CLIl \& adjacent area to target haddock w/ separator trawl |
|  | Oct - EGB area closed to multispecies DAS permits |
| 2005 | Jan - Eastern US/CA area reopened |
|  | Apr-Eastern US/CA area closed until April 30 |
|  | Aug -Eastern US/CA area closed )GB cod TAC projected near 90\%) |
| 2006 | Eastern US/CA haddock SAP delayed opening until Aug. 1 |
| 2007 | april 25 - Eastern US/CA area closed until Apr. 30 |
|  | Jun - Eastern US/CA area closed to limited access multispecies TAC (due to cod catch) |
|  | Oct- Eastern US/CA area open to limited access multispecies TAC |
|  | Nov- Eastern US/CA area closes |
| 2008 | May- Eastern US/CA area delayed opening until Aug. 1; |
|  | Jun- Eastern US/CA area delayed opening until Aug. 1 for all gear (prevent catching 1st qtr cod TAC) |
| 2009 | May-Eastern US/CA area closed until Aug. 1 for trawl vessels |
| 2010 | Apr-Eastern US/CA area closed ; May 1 opening delayed until August |

Table 3. Nominal landings (mt) of cod from eastern Georges Bank by gear and month for Canada, 20032012.

| Year | Gear | Jan | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec | Total |

Table 9. Calibration factors at length used to adjust for differences between the catches of cod by the NMFS research vessels FSV Henry B. Bigelow and FRV Albatross IV. The factors are applied to cod numbers at length collected on the Bigelow during spring and fall surveys since 2009.

| Length (cm) Calibration Factor |  |
| ---: | ---: |
| 1 to 20 | 5.723743 |
| 21 | 5.600243012 |

## APPENDIX A. 2013 STATISTICAL CATCH AT AGE (ASAP) MODEL UPDATE FOR EASTERN GEORGES BANK ATLANTIC

## INTRODUCTION

This assessment presents an update of the statistical catch at age model 'Age Structured Assessment Program' (ASAP) reviewed at the 2012 April Eastern Georges Bank cod benchmark model meeting. The ASAP model was not chosen by then TRAC as a benchmark model for stock status or catch advice; however, the TRAC agreed to apply the ASAP model results in a consequence analysis of projection results.

The ASAP model was chosen to explore as an alternative model to the virtual population model (VPA) during the EGB cod benchmark in part because ASAP had recently been accepted as the new benchmark model for the US GB cod assessment, replacing the VPA that had historically been applied since 1978 (NEFSC, 2013). Prior to 2004, both the EGB and GB cod assessments had been conducted with VPA and had similar formulations. After the 2002 EGB cod benchmark review (O'Boyle and Overholtz, 2002) the assessments started to diverge. While it is not mandatory that the two assessments be similarly formulated, given that EGB cod data is in both assessments, it would be appropriate to have the populations on the same scale. Also, given that part or all of the Georges Bank cod stock is managed by both the TMGC and the NEFMC, respectively, similarly scaled populations would allow for compatibility in management decisions.
ASAP was used to derive estimates of instantaneous fishing mortality in 2012 and stock size in 2012. A retrospective analysis was performed for terminal year fishing mortality, spawning stock biomass, and age 1 recruitment. Stochastic projections from model result were performed to provide estimated landings and spawning stock biomass (SSB) in 2014-2015.

## ASSESSMENT MODEL FORMULATION

## Model Description

ASAP, a forward projecting statistical catch at age model (Legault and Restrepo, 1998) can be downloaded from the NOAA Fisheries Toolbox (NFT, http://nft.nefsc.noaa.gov/). As described at the NFT software website, ASAP is an age-structured model that uses forward computations assuming separability of fishing mortality into year and age components to estimate population sizes given observed catches, catch-at-age, and indices of abundance. Discards can be treated explicitly. The separability assumption is partially relaxed by allowing for fleet-specific computations and by allowing the selectivity at age to change in blocks of years. Weights are input for different components of the objective function which allows for configurations ranging from relatively simple age-structured production models to fully parameterized statistical catch at age models.

The objective function is the sum of the negative log-likelihood of the fit to various model components. Catch at age composition is modeled assuming a multinomial distribution. Surveys can be treated as either "west coast style" in the same manner as the catch data with a total survey time series and survey catch at age composition modeled assuming a multinomial distribution, or "east coast style" with the survey indices at age entered as separate series. Most other model components are assumed to have lognormal error. Specifically, lognormal error is assumed for: total catch in weight by fleet, survey indices, stock recruit relationship, and annual deviations in fishing mortality. Recruitment deviations are also assumed to follow a lognormal distribution, with annual deviations estimated as a bounded vector to force them to sum to zero (this centers the predictions on the expected stock recruit relationship). For further details, the reader is referred to the technical manual (Legault, 2008).

## Data Input

Input to the ASAP model is the same as the VPA and includes the total catch (mt) for the combined landings and discards of USA and Canadian fleets (Table $1^{1}$, Figure $2^{1}$ ), and the catch-at-age (Table $6^{1}$ Figure $14^{1}$ ) and weight-at-age (Table $7^{1}$, Figure $15^{1}$ ) for ages 1-10+ during 1978-2012. Beginning year weight-at-age is back-calculated from the mid-year catch weight-at-age (Table A1) and also estimated from an average of the DFO and NEFSC spring research survey weight-at-age (Table $16^{1}$ ). Swept-area population estimates derived from indices of abundance include the Canadian DFO 1986-2012 estimates for ages 1-10+ (Table $10^{1}$, Figure $21^{1}$ ), the NEFSC 1978-2012 standardized spring estimates for ages 1-10+ (Table $11^{1}$, Figure $21^{1}$ ), and the NEFSC 1978-2012 standardized autumn estimates for ages 1-6 (Table $12^{1}$, Figure $21^{1}$ ). The NEFSC spring survey was dis-aggregated into two series based on the use of the Yankee \#41 otter trawl from 1978-1981 and the Yankee \#36 otter trawl after that time. Maturity was age and time invariant and knife edge maturity was assumed at age 3 as in previous EGB cod assessments. Natural mortality was age and time invariant and was assumed to be 0.2 as in previous assessments (Wang and O'Brien 2012).

## Model Formulation

The ASAP model was updated using the model run3f. 1 formulation presented and reviewed at the April 2013 benchmark. A multinomial distribution was assumed for both fishery catch at age and survey age compositions. The survey time series were not split between 1994/1995 as had been done in previous EGB cod VPA formulations (Wang and O'Brien, 2012). The catch CV was set equal to 0.05 and the recruitment $C V$ set equal to 0.5 ; however, the recruitment deviations were set with lambda $=0$, so the deviations did not contribute to the objective function.

Both the fishery and survey selectivity was modeled as 'flat-topped'. For the fisheries, two selectivity blocks were modeled as single logistic from 1978-1993 and 1994-2012.
The effective samples size (ESS) of the catch and surveys were adjusted based on interpretation of the so-called 'lanelli' plots (McAllister and lanelli, 1997). The input ESS is compared to the model predicted ESS; an appropriate ESS is considered to be that which intersects the input ESS.
The catch ESS was set at 75 for 1978-1995 and 125 for 1996-2012, and the ESS for each survey was set at 50.
At the 2012 benchmark the CV for each survey was initially set at the value generated from the survey estimate of stratified mean number per tow (DFO STRANAL). For the DFO survey the CVs averaged 0.31 , with a range of $0.15-0.66$, for the NEFSC spring the CVs averaged 0.32 , with a range of 0.13-0.83, and for the NEFSC autumn survey the CVs averaged 0.47 , with a range of $0.24-0.88$. Further examination of the model fits to the survey indices resulted in adding the following constant to each survey CV vector: 0.25 (DFO), 0.3 (NEFSC spring \#36), and 0.2 (NEFSC autumn), except the NEFSC spring \#4, which was not adjusted. These same values were added during this 2013 update.

## Model Results

Model results, including the objective function (OF), number of parameters, components to the OF, the root mean square error (RMSE), computed from standardized residuals, and SSB and fishing mortality ( $F$ ) estimates are summarized in Table A2 for all model runs conducted.

[^0]A bridge ASAP run was conducted to include corrected coefficient of variation (CV) estimates for the NMFS 2009-2011 survey abundance estimates. Comparing the differences between the benchmark ASAP model formulation and the corrected CV model, both with terminal year =2011, shows little differences in the OF or the RMSE. The updated CV run resulted in slightly higher $F$ and SSB in 2011.

BASE 2013 ASAP
The bridge run was updated with 2012 catch and survey and results described below.
Catch
The model fit to the observed catch is almost exact with the CV of 0.05 assigned to the commercial catch (Figure A1). The catch age composition exhibits larger residuals in the early time period, with a pattern of negative residuals for age 3 (Figure A2). The magnitude of the input ESS appears appropriate given that the predicted ESS generally bisects the observed ESS (Figure A3).

Indices
The fit of the predicted indices through the observed DFO survey indices was better during the period 1995-2000 than before or after that period; in recent years the model fit does not bisect the survey confidence bounds for all years (Figure A4). A pattern of negative residuals in the older age groups during 1986-1995 and in the younger ages during 2000-2011 is apparent in the age composition (Figure A5). The final DFO survey ESS was set at 50 and appears appropriate given that the predicted ESS generally bisects the observed ESS (Figure A6).

The fit of the predicted indices through the NEFSC autumn survey indices did not show any strong patterning, although in recent years the model fit does not bisect the survey confidence bounds for all years (Figure A7). The maximum residual of the age composition is the largest of the 4 surveys at 0.36 (Figure A8). The age 1 residuals are large and have a positive values in the early years and a negative pattern in the later years, however the older ages do not exhibit this pattern (Figure A8). The final input ESS was set = 50 and appears appropriate given that the predicted ESS generally bisects the observed ESS (Figure A9).

The model fit diagnostics for the NEFSC spring (Yankee \#41) are presented in Figures A10A12. With only 4 years of survey indices, no patterns are easily described or evaluated.

The fit of the predicted indices through the NEFSC spring (Yankee \#36) survey indices indicated, similar to the DFO survey, a series of negative residuals in the late 1980s to 1994 and a series of positive residuals since the mid-2000s (Figure A13). The residuals of the age composition show a pattern of positive residuals in age 2 and negative in age 4 in the early years and the opposite in the later years (Figure A14). The input ESS was set = 50 and appears appropriate given that the predicted ESS generally bisects the observed ESS (Figure A15).

Fishing Mortality, SSB, and Recruitment
Fully recruited F (unweighted, ages 5+) was estimated at 0.44 in 2012 (Table A3, Figure A16), a 44\% decrease from 2011. SSB in 2012 was estimated at 1,922 mt, a 4\% increase from 2011 (Table A3, Figure A16). Recruitment (millions of age 1 fish) of the 2003 year class ( 2.5 million) is now estimated to be smaller than the 1998 year class ( 3.4 million), the 2010 year class is estimated at 2.1 million, and the 2011 year class is the 3rd smallest year class estimated at 0.5 million (Table A3, Figures A16-A17).

Retrospective Analysis
A retrospective analysis was performed to evaluate how well the ASAP calibration would have estimated F, SSB, and recruits at age 1 for seven years (2005-2011) prior to the terminal year,
2012. The pattern of overestimating SSB and underestimating $F$ relative to the terminal year, as observed in the VPA (Wang and O'Brien, 2012), is not very strong in this model for F and SSB, but there is a pattern of underestimating recruitment relative to the terminal year estimate (Figure A18). The retrospective rho values, the average of the last 7 years of the relative retrospective peels, were 0.23 for SSB, -0.17 for F5+, and -0.35 for recruitment. Applying a retrospective adjustment ((1/(1+rho)) * estimate) results in 2012 estimates of $\mathrm{F}=0.53$, $\mathrm{SSB}=1,567 \mathrm{mt}$, age 1 recruitment $=0.69$ million fish.

## Model Uncertainty - MCMC

A Monte Carlo Markov chain (MCMC) simulation was performed to estimate uncertainty in the model estimates. The MCMC provides posterior probability distributions of the SSB and average F5+ time series. Two MCMC chains of initial length of 5.0 million were simulated with every 2,500th value saved. The trace of each chain's saved draws suggests good mixing for both SSB and $F$ (Figure A19). The lagged autocorrelations showed decreased correlation with increased lag with correlations $\leq 0.1$ beyond lag 0 for SSB and F (Figure A20). From the MCMC distributions, a $90 \%$ probability interval ( PI ) was calculated to provide a measure of uncertainty for the model point estimates for SSB and average F5+. Time series plots of the $90 \%$ PIs as well as plots of the posterior probability distributions for SSB2012 and average F5+ are shown in Figures A21-A22.

The 2012 SSB MCMC estimate of $1,910 \mathrm{mt}$ has a $90 \%$ PI of $1,317 \mathrm{mt}-2,832 \mathrm{mt}$ and the 2012 MCMC average F5+ $=0.45$ has a $90 \% \mathrm{PI}$ of $0.28-0.71$.

## SENSITIVITY RUN

The base ASAP model was run using Jan. 1 back-calculated mean weight at age based on the Rivard method (Rivard, 1982). A sensitivity run was done using January ${ }^{\text {st }}$ weight at age based on an average of the DFO and NMFS spring survey data. The results (Table A2) indicate minimal differences when applying these two weight-at-age matrices.

## BIOLOGICAL REFERENCE POINTS

## Yield per Recruit Analysis

For the 2013 cod model benchmark, a yield per recruit (YPR) analysis was conducted using the methods of Thompson and Bell (1934). Input data for catch and stock weights (ages 1-10+) were derived from an average of the most recent five years (2007-2011). The partial recruitment (PR) was based on a normalized arithmetic mean of 2007-2011 total fishing mortality from the ASAP model run3f.1. The maturity ogive was knife-edge at age 3. Results of YPR analysis are presented below. The current negotiated EGB cod $F$ reference point is $F_{\text {ref }}$ $=0.18$ (TMGC meeting December 2002). (The current GB cod $F_{\text {MSY }}$ proxy $=F_{40 \%}=0.18$ ).

|  | F |
| :--- | ---: |
| F0.1 | 0.19 |
| fmax | 0.43 |
| F30\% | 0.29 |
| F40\% | 0.19 |
| Fcurrent | 0.45 |

EGB cod is not managed by biomass reference points, however, for background purposes, nonparametric estimates of MSY and SSB $_{\text {MSY }}$ based on $\mathrm{F}_{40 \%}$ were estimated using the 34 -year time series mean recruitment ( 5.484 million age 1 fish), Y/R (1.22) and SSB/R (7.18) as: $\mathrm{F}_{40 \%}=0.19$, $\mathrm{MSY}=6,677 \mathrm{mt}$, SSB $_{\text {msy }}=39,353 \mathrm{mt}$.

The yield per recruit analysis was not updated with the 2013 June ASAP results.

## MSY Biological Reference Points

Long-term Stochastic Projection

For the 2013 cod model benchmark, long term (100 years) stochastic projections were run using the same input data as the YPR with $F_{\text {ref }}=0.18$. Following the GB cod accepted assessment projection formulation (NEFSC 2013), recruitment was estimated from a 2 stage cumulative distribution function (CDF) based on either 19 low estimates or 14 high estimates of age 1 recruitment. Based on a visual examination of the stock recruit plot (Figure A17), when SSB is $<15,000 \mathrm{mt}$ recruitment is drawn from the low recruitment CDF, and when SSB >15,000 mt then recruitment is drawn from the high recruitment CDF.

The long term projection provided the following non-parametric biomass reference points:
$\mathrm{F}_{\mathrm{REF}}=0.18$,
MSY = 11,059 mt ( $80 \% \mathrm{Cl}: 2,065 \mathrm{mt}-14,180 \mathrm{mt}$ ),
SSB $_{\text {MSY }}=30,622 \mathrm{mt}$ ( $80 \% \mathrm{CI}: 25,450 \mathrm{mt}-84,346 \mathrm{mt}$ ).

## PROJECTIONS

Short term stochastic projections under $\mathrm{F}_{40 \%}$ were performed from the updated 2013 ASAP model results to estimate landings and SSB during 2014. The input values for mean catch and stock weights, partial recruitment (PR), and maturity were estimated as 3-year averages from 2010-2012. Recruitment was estimated using the 2-stage CDF described above and associated with a SSB breakpoint of $15,000 \mathrm{mt}$. Catch in 2013 was estimated based on assumption that the 2012 quota would be caught.

The results of the short term projections indicate under the $\mathrm{F}_{\text {ref }}=0.18$ catch is projected to increase each year through 2015, and SSB is also projected to increase in each year through 2015.

| Year | SSB | F | Catch |
| :--- | :--- | ---: | ---: |
| 2013 | 3476 | 0.27 | 600 |
| 2014 | 3937 | 0.18 | 601 |
| 2015 | 4520 | 0.18 | 710 |

## SUMMARY DISCUSSION

Productivity of EGB has been low for the last two decades with poor recruitment and truncated age structure. An increase in natural mortality may have contributed to the recent low productivity; however, food habits data do not support this hypothesis (NEFSC, 2013b). Analysis of tagging data indicates minimal increase in M from the 1980s to the 2000s, and thus does not appear sufficient to explain the long term low productivity. Lack of large numbers of older repeat spawners in the EGB cod population since the mid-1980s may contribute to the long-term low productivity. Cod have a low success rate of hatching for first and second time spawners ( $13 \%$ and $62 \%$ ) until the third spawning (100\%), suggesting that an expanded age structure of fish that have spawned 3 or more times would contribute to higher productivity (Trippel 1998). Long-term overfishing may have also had indirect effects. Fishing activity disrupts the spawning aggregation and thus behaviors and rituals of cod, reducing the potential of good recruitment (Dean, 2012). Spawning of cod involves complex behaviors that have only recently been observed including arrival and departure of fish on the spawning ground at different times dependent upon sex, age, and stage of maturity (Lawson and Rose, 2000) and the formation of spawning leks, where the males set up and defend territory (Windle and Rose, 2007).

The update model formulation exhibits minimal retrospective bias in F and SSB that had been prevalent in previous assessments, however, additional variability was added to the survey abundance estimates, thus placing more emphasis on the catch data.
