APPENDIX A. 2014 STATISTICAL CATCH AT AGE (ASAP) MODEL UPDATE FOR EASTERN GEORGES BANK ATLANTIC COD ..... 76

#### Abstract

The combined 2013 Canada/USA Atlantic cod catches were 463 mt with a quota of 600 mt , which was the lowest catch since 1978. Catches from the 2014 Fisheries and Oceans Canada (DFO) and National Marine Fisheries Service (NMFS) spring surveys decreased from 2012, and both indices were among the lowest in the time series. Both the fishery and the survey catches showed truncated age structure in recent years.

The Virtual Population Analysis (VPA) "M 0.8" model from the 2013 benchmark assessment was used to provide catch advice. In this model, natural mortality (M) was assumed to be 0.2 except $\mathrm{M}=0.8$ for ages $6+$ since 1994. A consequence analysis to understand the risks associated with assumptions of the VPA "M 0.8 " and ASAP "M 0.2 " model (with constant $M=0.2$ ) was examined in the projection and risk analysis.

While management measures have resulted in a decreased exploitation rate since 1995, total mortality has remained high and adult biomass has fluctuated at a low level. The adult population biomass at the beginning of 2014 was estimated at $11,719 \mathrm{mt}$, which was about $20 \%$ of the adult biomass in 1978. Fishing mortality was high prior to 1994 and was estimated to be 0.04 in 2013, the lowest on record. Recruitment at age 1 has been low in recent years. The 2003 year class was estimated to be the highest recruitment since 2000. The initial estimate of the 2010 year class was stronger than the 2003 year class based on the 2014 assessment. Lower weights at age in the population in recent years and poor recruitment have contributed to the lack of rebuilding.

For the VPA "M 0.8" model, Transboundary Resources Assessment Committee (TRAC) agreed that $\mathrm{F}=0.11$ was an appropriate fishing mortality reference point. A $50 \%$ probability of not exceeding an $F=0.11$ implies catches less than $1,150 \mathrm{mt}$. However, given the extremely low Spawning Stock Biomass (SSB), stock rebuilding should be promoted. Even with no fishing in 2015, there would be a higher than $50 \%$ risk that 3+ biomass will decrease between 2015 and 2016.

For the consequence analysis, a catch of $1,150 \mathrm{mt}$ at $\mathrm{F}=0.11$ would result in a decrease in biomass of $10 \%$ in the VPA "M 0.8 " model and a decrease of $5 \%$ in the ASAP "M 0.2 " model. A catch of 489 mt at $\mathrm{F}_{\text {ref }}=0.18$ would result in at least a minimum $10 \%$ increase in the 2016 biomass based on the ASAP "M $0.2^{\prime \prime}$ model; however, the biomass in 2016 would decrease by $5 \%$ based on the VPA "M 0.8 " model.

## RÉSUMÉ

En 2013, les prises de morues franches combinées du Canada et des États-Unis se sont chiffrées à 463 tm , sur un quota de 600 tm , soit le total le plus bas depuis 1978. Les prises des relevés de printemps de 2014 effectués par Pêches et Océans Canada (MPO) et le National Marine Fisheries Service (NMFS) ont diminué par rapport à 2012, et les deux indices étaient parmi les plus faibles de la série chronologique. Au cours des dernières années, les prises de la pêche et des relevés ont montré une structure selon l'âge tronquée.

Le modèle d'analyse de population virtuelle (APV) «M=0,8 » de l'évaluation de référence de 2013 a été utilisé pour faire des recommandations en matière de prises. Dans ce modèle, la mortalité naturelle $(M)$ est estimée à 0,2 , sauf pour les individus de 6 ans et plus, où $M=0,8$ depuis 1994. Dans la projection et l'analyse des risques, on a examiné les résultats d'une analyse des conséquences, afin de comprendre les risques associés aux hypothèses du modèle d'APV «M=0,8» et du modèle du Programme d'évaluation selon la structure d'âge (PESA) « $M=0,2$ » (avec la constante $M=0,2$ ).

Quoique les mesures de gestion aient eu pour effet de faire baisser le taux d'exploitation depuis 1995, la mortalité totale est demeurée élevée et la biomasse des adultes a fluctué tout en restant faible. La biomasse de la population adulte était estimée à 11719 tm au début de 2014, ce qui correspondait à environ $20 \%$ de la biomasse des adultes de 1978. La mortalité par pêche était élevée avant 1994 et elle a été estimée à 0,04 en 2013 , soit le niveau le plus faible jamais enregistré. Le recrutement à l'âge 1 a été faible ces dernières années. On estime que la classe d'âge de 2003 représente le plus fort recrutement depuis 2000. En fonction de l'évaluation de 2014, on a initialement estimé que la classe d'âge de 2010 était plus abondante que la classe d'âge de 2003. Au cours des dernières années, les plus faibles poids selon l'âge au sein de la population et le faible recrutement ont nui au rétablissement du stock.
Pour le modèle d'APV «M=0,8 », le Comité d'évaluation des ressources transfrontalières (CERT) a convenu que $F=0,11$ était un point de référence relatif à la mortalité par pêche approprié. Une probabilité de $50 \%$ que le taux de mortalité par pêche ne dépasse pas $F=0,11$ suppose des prises inférieures à 1150 tm . Cependant, étant donné le niveau extrêmement faible de la biomasse du stock reproducteur (BSR), on devrait favoriser le rétablissement du stock. Même en l'absence de pêche en 2015, il y aurait un risque supérieur à $50 \%$ que la biomasse des individus de 3 ans et plus diminue entre 2015 et 2016.
Pour l'analyse des conséquences, une prise de $1,150 \mathrm{tm}$ à $F=0,11$ entraînerait une diminution de $10 \%$ de la biomasse selon le modèle d'APV «M=0,8», ainsi qu'une diminution de $5 \%$ selon le modèle du PESA « $M=0,2$ ». Des prises de 489 tm à $F_{\text {réf }}=0,18$ donneraient lieu à une augmentation d'au moins $10 \%$ de la biomasse en 2016, selon le modèle du PESA « $M=0,2 »$. Toutefois, la biomasse en 2016 diminuerait de $5 \%$, selon le modèle d'APV « $\mathrm{M}=0,8$ ».

## INTRODUCTION

The basis and background for the delineation of management units of cod on Georges Bank and the vicinity were reviewed and summarized at the 2009 Eastern Georges Bank cod benchmark assessment meeting (O'Brien and Worcester, 2009). For the purpose of a sharing agreement and consistent management by Canada and the USA, agreement was reached that the transboundary management unit for Atlantic cod would be limited to the eastern portion of Georges Bank (DFO Statistical Unit Areas 5Zej and 5Zem; USA Statistical Areas 551, 552, 561 and 562) (DFO, 2002). The management area is shown in Figure 1. The USA has a requirement for management advice for the Georges Bank cod stock (5Z + Subarea 6). The status quo has been to use an assessment of cod in 5Zjm for transboundary management advice and an assessment of cod in $5 Z+6$ for USA domestic management advice. While other options could be followed, this option is less disruptive to the existing processes.

The model formulations established by the 2009 Eastern Georges Bank cod benchmark assessment (Wang et al., 2009) were used for the eastern Georges Bank cod assessment from 2009 to 2012. In recent assessments the results exhibited persistent strong retrospective patterns. The retrospective analysis showed a tendency to overestimate biomass and underestimate fishing mortality in recent years (Wang and O'Brien, 2012). An Eastern Georges Bank cod benchmark assessment was conducted in 2013 to address these concerns, and the details of the model formulations that were agreed upon were documented in the proceedings (Claytor and O'Brien, 2013).

The current assessment applied the 2013 benchmark formulations using Canadian and USA fishery information updated to 2013, including commercial landings and discards, the Fisheries and Oceans Canada (DFO) survey updated to 2014, the National Marine Fisheries Services (NMFS) spring survey updated to 2014 and the NMFS fall survey updated to 2013.

## FISHERY

## COMMERCIAL FISHERY CATCHES

Combined Canada/USA catches averaged 17,198 mt between 1978 and 1993, peaked at $26,463 \mathrm{mt}$ in 1982, and then declined to $1,683 \mathrm{mt}$ in 1995. They fluctuated around $3,000 \mathrm{mt}$ until 2004 and subsequently declined again. Catches in 2013 were 463 mt , including 54 mt of discards (Table 1, Figure 2). Catches include USA and Canadian discards in all years where discard estimates were available.

Canadian catches peaked at $17,898 \mathrm{mt}$ in 1982 and declined to $1,140 \mathrm{mt}$ in 1995 (Table 1, Figure 3). Since 1995, with lower cod quotas, the fishery has reduced targeting for cod through changes in fishing practices, including the introduction of the cod separator panel for bottom trawls in 1999 (Table 2). From 1995-2012, Canadian catches fluctuated between 468 mt and $3,405 \mathrm{mt}$ (Table 1). In 2013, total catch (extracted landings on May 26, 2013; 395 mt ), including discards, was 424 mt against a quota of 513 mt , taken primarily between June and December by otter trawl and longline (Table 3, Figure 4 and 5). All 2013 landings were subject to dockside monitoring and at sea observers monitored close to $78 \%$ by weight of the mobile gear fleet landings, $29 \%$ by weight of the fixed gear landings and $19 \%$ of the gillnet fleet landings.
Canadian regulations prohibit the discarding of undersized fish from the groundfish fishery. For the Canadian groundfish fishery on eastern Georges Bank during 1978-1996, a review was conducted at the 2013 benchmark meeting to evaluate cod discards (unreported catch). Comparison of length frequencies of observer and port samples from otter trawl vessels did not provide evidence of discarding. Since there was little quota regulation of the Canadian Georges

Bank cod fishery prior to 1995, landings generally were well below the quota, it was concluded that there was no indication of discarding before 1996 (Claytor and O'Brien, 2013). For the Canadian groundfish fishery from 1997 to 2013, the ratio of sums method, which uses the difference in ratio of cod to haddock from observed and unobserved trips, was applied to estimate discards of cod. (Van Eeckhaute and Gavaris, 2004; Gavaris et al., 2006, 2007a) (Table 1). Cod discards from the 2013 Canadian groundfish fishery were estimated at 11 mt from the mobile gear and 10 mt from the fixed gear fishery (Table 1).

Since 1996, the Canadian scallop fishery has not been permitted to land cod. Landings until 1995 included those catches reported by the scallop fishery. The 3-month moving average observed discards rate has been applied to scallop effort to estimate discards from scallop fishery since 2005 (Gavaris et al., 2007b). Estimated discards of cod by the Canadian scallop fishery ranged between 29 mt to 200 mt annually since 1978 (Van Eeckhaute et al., 2005). In 2013, estimated discards of cod by the Canadian scallop fishery were 18 mt (Table 1).

USA catches increased from 5,502 mt in 1978 to 10,550 mt in 1984. With the implementation of the International boundary (the 'Hague Line') between Canada and the United States in 1984 (International Court of Justice 1984), catches declined and subsequently fluctuated around 6,000 mt between 1985 and 1993 (Table 1, Figure 3). Since December 1994, a year-round closure of Area II (Figure 1) has been in effect, with the exception of less than 3 scallop trips per year in 1999-2000, 2004-2006, 2009, and 2011-2013 and a haddock Special Access Program in 2004 (from August $1^{\text {st }}$ to the following January $31^{\text {st }}$ ) and since 2010. Minimum mesh size limits were increased in 1994, 1999, and 2002. Quotas were introduced in May 2004. Limits on sea days, as well as trip limits, have also been implemented (Table 2). With the implementation of a catch share system in 2010, most of the fleets are now managed by quotas. USA catches during 1994-2000 ranged between 544 mt and $1,204 \mathrm{mt}$ and increased to $1,935 \mathrm{mt}$ in 2003, then subsequently declined. Total USA catch (landings and discards combined) was 39 mt for calendar year 2013. The majority of USA landings are usually taken by the second calendar quarter with the least amount landed during the third quarter (Figure 5). Otter trawl gear accounted for 92\% and gillnet gear about 8\% of the landings during 2013.
Discards by USA groundfish fleets occur because of trip limits and minimum size restrictions. In September 2008, the 'Ruhle trawl', which reduces by-catch of cod, was authorized for use on eastern Georges Bank. Cod discarded in the eastern Georges Bank area by otter trawl and scallop fisheries were estimated using the Northeast Fisheries Science Center (NEFSC) Observer data from 1989-2013. A ratio of discarded cod to total kept of all species (d:k) was estimated on a trip basis. Total discards ( mt ) were estimated from the product of $\mathrm{d}: \mathrm{k}$ and total commercial landings from the Eastern Georges Bank area. In the 2012 Northeast Regional Stock Assessment Workshop (SAW) SAW55 cod benchmark meeting, 'Delphi' determined mortality rates (otter trawl: 75\%) were applied to the final estimates of USA discards (Table 1). The estimated discards of cod in the groundfish fishery were 15 mt in 2013, a $71 \%$ decrease from 52 mt discarded in 2012 (Table 1, Figure 3).

## SIZE AND AGE COMPOSITION

The size and age compositions of the 2013 Canadian groundfish fishery landings were derived from port and at-sea samples from all principal gears and seasons (Table 4, Figure 6). There were representative samples from the mobile gear and fixed gear fishery over all the fishing months. At-sea samples were pooled with port samples to derive catch at length and age. Landings peaked at $52 \mathrm{~cm}(20 \mathrm{in})$ for bottom trawlers and $67 \mathrm{~cm}(26 \mathrm{in})$ for longliners. Gillnetters caught fewer cod but these fish were larger, peaking at $70 \mathrm{~cm}(28 \mathrm{in})$ (Figure 7). The combined landings for all gears peaked at 52 cm (20 in) (Figure 8).The size composition of cod discards from the 2013 Canadian scallop fishery was derived from at-sea sampling. Cod discards from the scallop fishery peaked at 34 cm (13 in) (Figure 7). The discards from the groundfish fishery
were assumed to have the same size composition as the groundfish landings. The Canadian combined cod discards in 2013 from the groundfish and scallop fisheries peaked at 34 to 49 cm (13 to 19 in ) (Figure 8).

The size and age compositions of the 2013 USA fishery landings on eastern Georges Bank were estimated using port samples of length frequencies and age structures collected from all principal gears and seasons by market category (Table 4). The size and age composition of discarded fish were estimated using at-sea observer samples of length frequency and commercial and NEFSC survey age keys from the same area and season. Landings in 2013 peaked at 56 cm (22 in) and discards peaked at 47 cm (19 in) (Figure 9).

The total catch composition of combined landings and discards for Canada and the USA is shown in Figure 10. Canadian catches peaked at 52 cm (20 in); and USA catches peaked at 59 cm (22 in).

Canadian catch-at-age composition was obtained by applying quarterly fishery age-length keys to the size composition. The age-length key from the 2013 DFO survey was used to augment the first quarter key.

The age composition of the 2013 USA landings was estimated by market category by applying age-length keys to the size composition pooled by calendar quarter, semi-annually, or annually depending on the number of available length samples. The USA sampling protocol is 1 sample per 100 mt of landings (i.e. where 1 length sample $=100$ fish and 1 age sample $=20-25$ fish). The 2013 age-length keys were supplemented with age samples from statistical areas 522 and 525 for the catch at age calculations.

Total discards at age from the USA groundfish and scallop fisheries (1989-2013), the Canadian groundfish fishery (1997-2013) and the Canadian scallop fishery (1978-2013) were all included in the assessment.

The 2013 combined Canada/USA fishery age composition, by number, was dominated by the 2010 year class at age 3 (52\%), followed by the 2009 year class at age 4 (24\%) and the 2011 year class at age 2 (15\%) (Table 5, Figure 11). By weight, the 2010 year class dominated the 2013 fishery (44\%) followed by the 2009 (31\%) and 2008 year classes (9\%) (Figure 11). The contribution of age 7 and older fish continued to be small in recent years, $1 \%$ by number and $3 \%$ by weight in 2013 (Table 5, Figures 11 and 12).

Fishery weights at age showed a declining trend starting in the early 1990s (Table 6, Figure 15). Compared to 2012, the weights at age in 2013 improved but still at lower levels.

## ABUNDANCE INDICES

## RESEARCH SURVEYS

Surveys of Georges Bank have been conducted by DFO each year (February/March) since 1986 and by NMFS each spring (April) since 1968 and each fall (October) since 1963. All surveys use a stratified random design (Figures 14 and 15). Most of the DFO surveys have been conducted by the CCGS Alfred Needler using a Western IIA trawl. A sister ship, the CCGS Wilfred Templeman, conducted the survey in 1993, 2004, 2007, and 2008. In 2006, another vessel, the CCGS Teleost, conducted 6 of the sets. Using data from a comparative paired trawl fishing experiment conducted in the southern Gulf of St. Lawrence, the analysis showed no significant difference in the catchability of cod between Alfred Needler and Teleost (Benoît, 2006). For the NMFS surveys, two vessels have been employed and there was a change in the trawl door in 1985. Vessel and door type conversion factors derived experimentally from comparative fishing (Table 7) have been applied to the survey results to make the series consistent (Forrester et al., 1997). Additionally, two different trawl nets have been used on the

NMFS spring survey, a modified Yankee 41 from 1973-81 and a Yankee 36 in other years, but no net conversion factors were available for cod. A new net and vessel (NOAA ship Henry B. Bigelow), with revised station protocols have been used to conduct the NMFS spring and fall surveys since 2009. Calibration factors by length were calculated for Atlantic Cod for the data collected by the Henry B. Bigelow to make the data equivalent to previous surveys conducted by former NOAA ship Albatross IV. The new research vessel/net combination tended to catch more cod at all lengths, but also proportionally more small cod. Length calibration factors (Brooks et al., 2010) were applied to the NMFS spring and fall survey results since 2009 (Table 8).

The spatial distribution of ages 3 and older cod caught during the 2013 NMFS fall, 2014 DFO and 2014 NMFS spring survey were similar to that observed from those surveys over the previous decade, with most fish concentrated on the northeastern part of Georges Bank (Figures 16-18).

The catch in numbers from the 2014 DFO survey was lower than 2013, among the lowest in the time series (1986-2014) (Table 9). The 2010 year class at age 4 was dominant ( $44 \%$ by number), followed by the 2011 year class at age 3 ( $30 \%$ by number). There was no catch of the 2007 year class at age 7 and no catch of fish older than 8 (Table 9, Figure 19).

Similar to the DFO survey, the 2014 NMFS spring survey catch decreased from 2013 and was among the lowest in the time series (Table 10). The 2010 year class at age 4 was dominant ( $52 \%$ by number), followed by the 2011 year class at age 3 ( $32 \%$ in number). There were no fish caught older than age 6 (Table 10, Figure 19).

The catch from the 2013 NMFS fall survey increased from 2012, but was below the average of the time series. The 2010 year class at age 3 and 2011 year class at age 2 were dominant (totaling $72 \%$ by number), and the 2013 year class accounted for $10 \%$ by number. There were no catches of fish older than age 4 (Table 11, Figure 19).

The coefficient of variation (CV) of stratified mean catch number/tow for the three surveys is shown in Tables 12-14 and Figure 20. Median CV values indicated the most variable catch of ages 1 and 8 for DFO survey, ages 7 and 8 for the NMFS spring survey, as well as ages 1 and 5 for the NMFS fall survey. The CVs were similar between the DFO and NMFS spring surveys and smaller compared to the NMFS fall survey values. The catch from all three surveys became more variable after mid-1990s, which might be caused by patchy distribution at low abundance.

With the exception of the 1996, 1998 and 2003 year classes and potentially the 2010 year class (all of which were below the time series average), the survey abundance at age (Tables 9-11, Figure 19) shows poor recruitment since the 1990 year class in all three surveys. The 2003 year class has appeared strong in the DFO and spring surveys until age 7 and in the fall surveys until age 3; however, they were disappearing very fast after. The 2010 year class was prominent in all three surveys. Compared with pre-1990 surveys, representation at older ages and younger ages in recent years continues to be poor (Tables 9-11, Figure 19).
For the survey swept area biomass, the 2013 NMFS fall survey biomass increased from the 2012, but still remains low. In 2014, both the DFO and NMFS spring survey biomasses decreased from 2013 and were among the lowest in the time series (Table 15, Figure 21).
The average weights at age derived from the DFO survey and NMFS spring survey were used to represent the population weight at age for the beginning of the year. All the weights at age display a declining trend since the early 1990s (Table 16, Figure 22). Weights at age in 2014 are higher than in 2013 except for ages 2, 4 and 9.
Fulton's condition factor ( K ), an indicator which uses observed weight and length to measure fish condition, was calculated using the data from all three surveys. In order to reduce the
impact of gonad weight, the post-spawning fish samples were used for the Fulton's K calculation. It showed notable downward trends in recent years from DFO and NMFS spring samples (Figure 23), although the NMFS spring survey does show an increasing trend since 2011. There were limited catches from the NMFS fall survey (Table 11), and the trend from those samples was not clear (Figure 23). All the three surveys show that fish conditions are improved in 2014.

The total mortality ( $Z$ ) was calculated by two age groups (ages 4 and 5 , and ages 6 to 8 ) using DFO and NMFS spring survey abundance indices, separately. It showed that Z of ages 4 and 5 has been lower than the older age group (Figure 24). $Z$ has been high throughout the assessment time period for both age groups (Figure 24) and increasing in recent years although relative F (fishery catch at age/survey abundance indices) declined significantly since mid1990s (Figure 25).

## HARVEST STRATEGY

The Transboundary Management Guidance Committee (TMGC) has adopted a strategy to maintain a low to neutral risk of exceeding the fishing mortality reference. At the 2013 benchmark meeting, it was agreed that the current $\mathrm{F}_{\text {ref }}=0.18$ (TMGC meeting in December, 2002) is not consistent with the VPA "M 0.8 " model, and a lower value for $\mathrm{F}_{\text {ref }}$ would be more appropriate (Claytor and O'Brien, 2013). When stock conditions are poor, fishing mortality rates should be further reduced to promote rebuilding.

## ESTIMATION AND DIAGNOSTICS

## CALIBRATION OF VIRTUAL POPULATION ANALYSIS (VPA)

At the benchmark assessment review in 2013, there was no consensus on a benchmark model; however, the TRAC did agree to provide catch advice based on a virtual population analysis (VPA) "M 0.8" model (Claytor and O'Brien, 2013). The VPA used fishery catch statistics and size and age composition of the catch from 1978 to 2013 (including discards). The adaptive framework, ADAPT (Gavaris, 1988), was used for calibrating the VPA with trends in abundance from three research bottom trawl survey series: DFO, NMFS spring and NMFS fall.
Computational formulae used in ADAPT are described by Rivard and Gavaris (2003a).
In this model, natural mortality (M) was assumed equal to 0.2 except for ages 6+ from 1994 onwards where $M$ was fixed at 0.8 . The data used in the model were:
$C_{a, t}=$ catch at age for ages $a=1$ to $10+$ and time $t=1978$ to 2013, where $t$ represents the year during which the catch was taken;
$I_{1, a, t}=$ DFO survey for ages $a=1$ to 8 and time $t=1986.17,1987.17 \ldots$ 2013.17, 2014.00;
$I_{2, a, t}=$ NMFS spring survey (Yankee 41) for ages $a=1$ to 8 and time $t=1978.28,1979.28$, 1980.28, 1981.28;
$I_{3,, \mathrm{a}, \mathrm{t}}=$ NMFS spring survey (Yankee 36), for ages $a=1$ to 8 and time $t=1982.28,1983.28 \ldots$ 2013.28, 2014.00; and
$I_{4, a, t}=$ NMFS fall survey, ages $a=1$ to 5 and time $t=1978.69,1979.69 \ldots 2012.69$, 2013.69.
The population was calculated to the beginning of 2014; therefore, the DFO and NMFS spring survey indices for 2014 were designated as occurring at the beginning of the year, i.e. 2014.00. The benchmark formulations assumed that observation errors for the catch at age data were negligible. Observation errors for the abundance indices at age were assumed to be independent and identically distributed after taking natural logarithms of the values. Zero
observations for abundance indices were treated as missing data as the logarithm of zero is not defined. Fishing mortality on age 9 for 1978 to 2013 was assumed to be equal to the population weighted average fishing mortality on ages 7 and 8 .

Estimation was based on minimization of the objective function:
$\sum_{s, a, t}\left(\ln I_{s, a, t}-\left(\hat{\kappa}_{s, a}+v_{a, t}\right)\right)^{2}$
, where $s$ indexes survey.
The estimated model parameters were:
$v_{\mathrm{a}, \mathrm{t}}=\ln N_{\mathrm{a}, \mathrm{t}}=\ln$ population abundance for $\mathrm{a}=2$ to 9 at beginning of 2014;
$K_{1, a}=\ln$ DFO survey catchability for ages $\mathrm{a}=1$ to 8 at time $\mathrm{t}=1986$ to 2014;
$K_{2, a}=\ln$ NMFS spring survey (Yankee 41) catchability for ages $a=1$ to 8 at time $t=1978$ to 1981;
$K_{3, a}=\ln$ NMFS spring survey (Yankee 36) catchability for ages $a=1$ to 8 at time $t=1982$ to 2014; and
$K_{4, a}=\ln$ NMFS fall survey catchability for ages $a=1$ to 5 at time $t=1978$ to 2013.
Statistical properties of the estimators were determined using conditional non-parametric bootstrapping of model residuals (Efron and Tibshirani, 1993; Rivard and Gavaris, 2003a).

The population abundance estimate of the 2012 year classes at age 2 at beginning of 2014 exhibited the largest relative bias of $22 \%$ and relative error of $76 \%$. The relative bias for other ages ranged between $3 \%$ and $5 \%$, and the relative error ranged between $40 \%$ and $23 \%$ (Table 17). Survey catchability ( $q$ ) at age progressively increased until age 5 for DFO and NMFS spring surveys (Figure 26). Survey catchability at age for the NMFS fall survey was very low (Figure 26).

The overall fit of model estimated biomass to the DFO, NMFS spring and NMFS fall surveys was generally consistent with the survey trends after 1994 (Figure 27). There were residual patterns which suggested obvious year effects (Figure 28). Average fishing mortality (F4-9) by time blocks for 1978-1993, 1994-2008 and the recent 5 years (2009-2013) was 0.48, 0.27 and 0.09 , respectively. The temporal trend of fishing mortality was consistent with fishery management effort trend. There was relatively flat fishery partial recruitment pattern except for the 10+ group (Figure 29).

Retrospective analysis was used to detect any bias of consistently overestimating or underestimating fishing mortality, biomass, or recruitment, relative to the terminal year estimates. At the 2013 benchmark meeting, the VPA "M 0.8 " model with catch data through 2011 did not show any retrospective pattern (Claytor and O'Brien, 2013), suggesting that model assumptions on natural mortality were appropriate and that the fishery catch at age was consistent with the survey indices. However, in the 2013 assessment with catch data through 2012 (Wang and O'Brien, 2013), the 2003 year class was estimated to be substantially smaller than the estimate from the 2013 benchmark model formulation with one less year of data. In the 2013 assessment, the 2003 year class was estimated at 4.1 million at age 1 compared to the benchmark estimate of 13.5 million, with one less year of data (Figures 30 and 31). The estimate was 4.4 million in the 2014 assessment, close to the 2013 assessment. Residuals of the 2003 year class from the three surveys were predominantly positive, which means that the 2003 year class was underestimated in both the 2013 and 2014 assessment (Figure 32). The 2014 assessment results were very close with the 2013 assessment, there was no consistent pattern.

Possible reasons for the appearance of a retrospective bias after adding one more year of data were explored. At the benchmark model review in 2013, with catch data through 2011 as described above, the age 9 in 2012 (2003 year class) was estimated directly as a model parameter. While in the 2013 and 2014 assessments, the determination of the 2003 year class relied on the 2012 fishery age 9 (2003 year class) catch and the assumption that F9 (2003 year class) is equal to the population weighted average $F$ on ages 7 and 8 of adjacent year classes. And there is no age 9 survey abundance indices applied to calibrate the catch-at-age matrix.

The prevalence of age 9 fish in the 2012 fishery catch was expected to be high based on the abundance of the 2003 cohort in each of the previous age classes. However, a proportionately low value of age 9 catch accounted for only $0.3 \%$ in number in the 2012 fishery catch, which led to a much lower estimate of this cohort and contributed to a retrospective bias.

The low catch of age 9 (2003 year class) in 2012 could be due to error in the fishery catch. Another possible reason might be the actual M experienced by the 2003 year class between ages 8 and 9 was higher than that assumed $\mathrm{M}=0.8$. Using the assumed M would artificially reduce the abundance of the entire 2003 cohort in the backward calculation (even if the 0.8 is a good approximation of M among ages 6 and 7). Sensitivity runs were conducted to explore the uncertainties in estimation of the 2003 year class. The impacts on the estimate of recruitment of other year classes, terminal year (2014) population abundance as well as the implication for the projection were investigated.

## Sensitivity Analyses

In the following sensitivity runs, the model set up was the same as the VPA "M 0.8 " model formulation described above for the 2014 assessment except for:

- Run 1: Estimating the 2003 year class (yc) at age 9 ('estimate 2003yc' model). In this model, the abundance of the 2003 year class at age 9 in 2012 was estimated as a parameter. Thus, neither age 9 fishery catch nor the assumption on $F$ at age 9 as an average of adjacent year classes was used in the estimation of the age 9 population number of the 2003 year class.
- Run 2: Removing the 2003 year class survey abundance indices entirely from the data input ('without 2003yc' model). In this sensitivity run, the abundance of the 2003 year class at age 9 was arbitrarily fixed at a value of 100 thousand. Since no 2003 year class survey abundance indices were used in the calibration and objective function, this fixed value has no impact on estimation of the other year classes.
The estimated 2003 year class numbers at age from run 1 were compared with the 2012 and 2014 assessments. The 2003 year class at age 1 from the "estimate 2003yc" model was very close to the 2012 assessment at about 13.5 million fish at age 1 , well above 4.1 million from the 2013 and 4.5 million from the 2014 assessment (Table 18, Figure 33). For recruitment in other years, the "estimate 2003yc" model had almost the identical results with the 2012 assessment; while the estimate from the 'without 2003yc' model was closer to the 2014 VPA "M 0.8 " model. The 2014 assessment with "M 0.8 " model estimated the 2010 year class at 5.6 million, while the 2 sensitivity runs estimated the year class at about 5.9 and 5.4 million (Table 18, Figure 34). Although the 2014 VPA "M 0.8" model tended to underestimate the size of year classes prior to 2003, the estimate for the most recent 3 year classes was very similar among all models (Table 18 and Figure 34).

For the terminal year population abundance estimate, the "estimate 2003yc" model had higher estimates for most age groups compared to the 2014 VPA "M 0.8" model. There were very minor differences between 'without 2003yc' model and 2014 VPA "M 0.8" model, except for age 9 (Table 18 and Figure 35).
For the terminal year biomass, the "estimate 2003yc" model had the highest estimate of age 10+ biomass at 915 mt with a deeply dome-shaped PR compared with 162 mt from the 2014

VPA "M 0.8" model. However, the difference in the terminal year ages 3-9 biomasses was minor between the VPA "M 0.8" model and 'without 2003yc' model (Table 18 and Figure 36).

The above sensitivity analyses suggested that the low estimate of the 2003 year class may be an outlier, which then caused a retrospective bias in the 2013 and 2014 assessment. Removing the 2003 year class abundance indices ("without 2003yc" model) showed that it had little impact on the estimation of other year classes in the terminal year (Table 18, Figure 35 and 36) or recruitments in other years (Table 18, Figure 34) compared with the 2014 assessment using the VPA "M 0.8" model.

Applying the retrospective adjustment was not appropriate and was not conducted in this assessment.

1) There is no consistent pattern in the retrospective analysis. As shown in the sensitivity analysis, the retrospective bias might be caused by natural mortality changes ( $Z \gg 1$ from surveys using catch curve analysis) or bias in fishery catch on older fish of the 2003 year class.
2) With dominant positive residuals, the residual plot (Figures 28 and 32) showed that the 2003 year class were underestimated in the 2013 and 2014 assessment from the "M 0.8" model. Retrospective adjustment would further underestimate the biomass.
3) The sensitivity analysis ("without 2003yc") showed that the 2014 assessment with the "M 0.8 " model gets very similar result with the "without 2003 yc" run (Table 18, Figures 34-36) when the effect of the 2003 year class was removed from the objective function. It illustrated the 2014 assessment with the VPA "M 0.8" model is robust to the uncertainties in the estimate of the 2003yc.

## STATE OF RESOURCE

Fixing the retrospective bias could be done by the "est 2003yc" model. However, the adult biomass, recruitment, and fishing mortality estimates were different from the VPA "M 0.8 " model (Figure 30). The estimates (Tables 19-21) presented below were from the 2012 benchmark VPA "M 0.8" model.

Adult population biomass (ages 3+) declined substantially from about 52,000 mt in 1990 to below $16,000 \mathrm{mt}$ in 1995, the lowest observed at that time (Table 19, Figure 37). Biomass has subsequently fluctuated between $5,900 \mathrm{mt}$ and $18,800 \mathrm{mt}$. The estimate of $3+$ biomass was $11,179 \mathrm{mt}(80 \%$ confidence interval: $1,0461 \mathrm{mt}-14,750 \mathrm{mt})$ at the beginning of 2014 (Table 19). The increase of $3+$ biomass during 2005-2009 was largely due to the recruitment and growth of the 2003 year class, and since 2011 was largely due to the recruitment and growth of the 2010 year class (Figure 38). High natural mortality, lower weights at age in the population in recent years, and generally poor recruitment have contributed to the lack of sustained rebuilding. Survey biomass indices have been lower since the mid-1990s (Figure 21). The estimated adult population biomass at the beginning of 2014 from the VPA was about one fifth of the 1978 biomass (Figure 37).
Recruitment at age 1 has been low in recent years (Table 20, Figure 37). Since 2000, the 2003 year class at 4.4 million fish at age 1 ( 13.5 million fish at age 1 from the 2012 assessment), had been the highest recruitment estimated. However, the initial estimate of the 2010 year class at 5.4 million age 1 fish is stronger than the 2003 year class based on the 2014 assessment. Both the 2003 and 2010 year classes are around half of the average (about 11 million age 1 fish) during 1978-1990, when the productivity was considered to be higher (Table 21, Figure 37). Recruitment for the 2002 and 2008 year classes are the lowest on record. The current biomass is well below $30,000 \mathrm{mt}$, above which there is expected to be a better chance for higher recruitment (Figure 39).

Fishing mortality (population number weighted average of ages 4-9) was high prior to 1994 (Table 21, Figure 40). F declined in 1995 to $F=0.11$ due to restrictive management measures and then fluctuated between 0.04 and 0.38. F in 2013 was estimated to be 0.04 ( $80 \%$ confidence interval: 0.036-0.051). The assessment showed recent reductions in F, and the 2013 fishing mortality was below $\mathrm{F}_{\text {ref }}=0.18$. However, because the current $\mathrm{F}_{\text {ref }}$ was based on an assumption of $\mathrm{M}=0.2$, the value is not appropriate for comparison with the VPA "M 0.8 " model results (Claytor and O'Brien, 2013).

Yield exceeded surplus production during the early 1990s (Figure 41). Surplus production since the mid-1990s has remained considerably lower than that prior to 1990. Growth of ages 2 to 10 has typically accounted for the greatest percentage of the production (Figure 38). Occasionally, a strong incoming year-class at age 2 makes a greater contribution to production. The 2003 year class made such a contribution in 2005. In 2012 and 2013, yield exceeded surplus production (Figure 41).

## PRODUCTIVITY

Recruitment, age structure, fish growth, and spatial distribution typically reflect changes in the productive potential. While management measures have resulted in a decreased exploitation rate since 1995, total mortality has remained high and adult biomass has fluctuated at a low level. The current biomass is well below $30,000 \mathrm{mt}$; when biomass is above this threshold, there is a better chance for higher recruitment (Figure 39). Average weight at length, used to reflect condition, has been stable in the past, but has started to decline in recent years. Size at age in the 2013 fishery remains low (Table 16). The research survey spatial distribution patterns of adult (age 3+) cod have not changed over the past decade (Figures 16-18). Lower weights at age in the population in recent years and poor recruitment have contributed to the lack of rebuilding.

## OUTLOOK

This outlook is provided in terms of consequences with respect to the harvest reference points for alternative catch quotas in 2014 (Gavaris and Sinclair, 1998; Rivard and Gavaris, 2003b). At the 2013 cod benchmark meeting (Claytor and O'Brien, 2013), the consensus was the current $\mathrm{F}_{\text {ref }}=0.18$ is not consistent with the VPA "M 0.8 " model given that it was derived based on models with an $M=0.2$, and a lower value for $F_{\text {ref }}$ would be more appropriate. At the 2014 TRAC meeting, it was agreed that $F=0.11$ was an appropriate fishing reference point for the VPA "M 0.8" model based on the analyses presented (O'Brien and Worcester, 2014). This value was derived from an age-disaggregated Sissenwine-Shepherd production model using $\mathrm{M}=0.8$ (Wang and O'Brien, 2013). TRAC recommends basing catch advice on $\mathrm{F}=0.11$.
Uncertainty about current biomass generates uncertainty in forecast results, which is expressed here as the probability of exceeding $F_{\text {ref }}=0.18$ or $F=0.11$ and as the change in adult biomass from 2015 to 2016. The risk calculations assist in evaluating the consequences of alternative catch quotas by providing a general measure of the uncertainties. However, risk calculations are dependent on the data and model assumptions and do not include uncertainty due to variations in weight at age, partial recruitment to the fishery, natural mortality, systematic errors in data reporting, or the possibility that the model may not reflect stock dynamics closely enough.
For projections, the average of the most recent three years of fishery and survey weights at age is used for fishery and beginning year population biomass for 2015 and 2016. The 2014 and 2015 partial recruitment pattern is based on the most recent five years of estimated partial recruitment (Table 22). The 2009-2013 geometric mean of recruitment at age 1 is used for 2014-2016 projections, the uncertainties for this estimate are not reflected in the projection. Catch in 2014 is assumed to be equal to the 700 mt quota, and $\mathrm{F}=0.18$ or $\mathrm{F}=0.11$ in 2015.

## PROJECTION BASED ON F REF $=0.18$

Table 23 shows the deterministic projection results, where the projected catch at $\mathrm{F}_{\text {ref }}=0.18$ would be $1,959 \mathrm{mt}$ in 2015. The stochastic projection indicates a combined Canada/USA catch of $1,850 \mathrm{mt}$ in 2015 will result at neutral risk of $F$ exceeding $F_{\text {ref }}=0.18$ (Table 24, Figure 42). Because $\mathrm{F}_{\text {ref }}=0.18$ is not consistent with the " M 0.8 " assessment model, it is inappropriate for catch advice.

## PROJECTION BASED ON F = 0.11

Both deterministic (Table 25) and stochastic (Table 24, Figure 42) projections based on $\mathrm{F}=0.11$ are provided. A $50 \%$ probability of not exceeding $\mathrm{F}=0.11$ implies a combined Canada/USA catch less than 1,150 mt (Table 24, Figure 42). Even with no fishing in 2015, there is higher than $50 \%$ risk that 2016 adult biomass will be lower than 2015. Catches of 225 mt will result in a higher risk (75\%) that 2016 adult biomass will not increase (Figure 42).

## SENSITIVITY ANALYSIS

To examine the effect of the uncertainties in the estimation of the 2003 year class, the "estimate $2003 y c "$ model is used as a sensitivity analysis for projections. The strong dome-shaped partial recruitment for ages 10+ from the model results is applied in the projection (Table 22). Deterministic (Table 25) and stochastic (Table 24, Figure 43) projections are provided. A 50\% probability of not exceeding $F_{\text {ref }}=0.18$ implies a combined Canada/USA catch less than $1,900 \mathrm{mt}$, and less than $1,200 \mathrm{mt}$ for $\mathrm{F}=0.11$. Even with no fishing in 2015 , there is higher than $50 \%$ risk that 2016 adult biomass will be lower than 2015. Catches of 175 mt will result in a higher risk (75\%) that 2016 adult biomass will not increase (Figure 43).
Given the extremely low biomass, management should try to realize the growth potential from the 2010 year class to rebuild the spawning stock biomass. In order to not exceed $F=0.11$, and to promote stock biomass rebuilding, catches must not exceed 175 mt based on above analysis (Table 24, Figure 42 and 43).

## CONSEQUENCE ANALYSIS (RISKS ASSOCIATED WITH 2015 PROJECTED CATCH)

The risks associated with potential management actions taken during 2015 are examined with a consequence analysis by undertaking stock projections under the competing assumptions of the 'state of nature'. The two states of nature are the VPA "M 0.8" model and the ASAP M 0.2 model, both presented at the 2013 cod benchmark model meeting (Claytor and O'Brien, 2013) and updated through 2014 for this 2014 assessment. At the benchmark model meeting, the TRAC agreed to apply the VPA "M 0.8 " model for providing catch advice; however, given that $F_{\text {ref }}=0.18$ is no longer consistent with that model, the TRAC also agreed to provide a consequence analysis of projected catch at two different fishing mortality rates from both models.

The analysis presents the consequences of management actions taken by setting projected catch according to the VPA "M 0.8 " model if the true state of nature is such that M has remained unchanged at 0.2 and stock productivity is best reflected by the ASAP M 0.2 model, and, conversely, if management actions were taken by setting projected catch according to the ASAP M 0.2 model (Appendix A) while the true state of nature is such that M has increased to 0.8 on older ages since 1994 and stock productivity is best reflected by the VPA "M 0.8 " model.

Data input to each model projection is as previously described for the VPA "M 0.8 " and for ASAP M 0.2 (Appendix A). These are short term projections, for one year to 2016, and do not account for any longer-term consequences.

The column headers in Table 26 represent the 'true' states of nature:
VPA M $0.8 \quad \mathrm{M}=0.2$ except $\mathrm{M}=0.8$ for ages $6+$ from 1994 onward
ASAP $0.2 \quad \mathrm{M}=0.2$ for all ages and all years
The row headers indicate the basis of the management action during the projected period (2015) for four different catches. The notation in parentheses indicates where that catch was derived, e.g., the row with a $1,150 \mathrm{mt}$ catch was projected from the VPA "M 0.8 " model at $F=0.11$. The cells of the table indicate the projected 2015 fully recruited $F$ and 2016 January $1^{\text {st }}$ ages 3+ biomass, and the projected percent increase in biomass from 2015 to 2016.

A catch of $1,150 \mathrm{mt}$ at $F=0.11$, would result in a decrease in biomass of $10 \%$ in the VPA "M 0.8 " model and $5 \%$ in the ASAP "M 0.2 " model. A catch of 489 mt at $\mathrm{F}_{\text {ref }}=0.18$ would result in at least a minimum 10\% increase in the 2016 biomass based on the ASAP "M 0.2" model; however, the biomass in 2016 would decrease by $5 \%$ based on the VPA " M 0.8 " model.

The consequence analysis reflects the uncertainties in the assessment model assumptions. Despite these uncertainties, all assessment results indicate that low catches are needed to promote rebuilding.

## SPECIAL CONSIDERATIONS

Table 27 summarizes the performance of the management system. It reports the TRAC advice, TMGC quota decision, actual catch, and realized stock conditions for this stock. Fishing mortality and trajectory of age 3+ biomass from the assessment following the catch year are compared to results from this assessment. These comparisons were kindly provided in 2011 by Tom Nies (staff member of the New England Fishery Management Council (NEFMC)) and updated for this assessment. The inconsistency of TRAC advice in the past with the realized stock conditions from the recent assessment was mainly due to the assessment model changes after the 2009 benchmark assessment, and the retrospective bias in the assessment also accounted for part of this inconsistency.

The consequence analysis reflects the uncertainties in the assessment model assumptions. Despite these uncertainties, all assessment results indicate that low catches are needed to promote rebuilding. In the ASAP model, the retrospective bias was not adjusted for 2014 and projected catches would be lower if the adjustments were done.

In July 2013, there was a reduction in the minimum size for the US fishery from 22 in to 19 in. This is expected to result in reduced discards and a possible change in PR for the youngest ages.

## ACKNOWLEDGEMENTS

We thank L. Van Eeckhaute for providing the Canadian discards data, B. Hatt of DFO and N . Shepherd for providing ageing information for the DFO and NMFS surveys and Canadian and USA fisheries, G. Donaldson and D. Frotten of DFO, and at sea observers from Javitech Ltd. for providing samples from the Canadian fishery.

Table 2. Canadian (a) and USA (b) fishery management history of cod on eastern Georges Bank, 1978 to 2013.

2a)

| Year | Canadian Management History |
| :---: | :---: |
| 1978 | Foreign fleets were excluded from the 200 mile exclusive economic zones of Canada and USA. |
| 1984 | October implementation of the maritime boundary between the USA and Canada in the Gulf of Maine Area. |
| 1985 | $5 Z$ cod assessment started in Canada; Set TAC; TAC $=25,000 \mathrm{mt}$. |
| 1986 | TAC $=11,000 \mathrm{mt}$ |
| 1987 | TAC $=12,500 \mathrm{mt}$ |
| 1988 | TAC $=12,500 \mathrm{mt}$ |
| 1989 | TAC = 8,000 mt; 5Zjm cod assessment. |
| 1990 | Changes to larger and square mesh size; <br> Changes from TAC to individual and equal boat quotas of 280,000 lbs with bycatch restrictions; Temporary Vessel Replacement Program was introduced. |
| 1991 | TAC = 15,000 mt; <br> Dockside monitoring; <br> Maximum individual quota holdings increased to $2 \%$ or 600 t (whichever was less). |
| 1992 | TAC = 15,000 mt; <br> Introduction of ITQs for the OTB fleet. |
| 1993 | TAC $=15,000 \mathrm{mt}$, ITQ for the OTB fleet not based on recommended catch quotas; OTB <65 fleet was allowed to fish during the spawning season (March-May $31^{\text {st }}$ ). |
| 1994 | TAC $=6,000 \mathrm{mt}$, <br> Spawning closures January to May $31^{\text {st }}$; <br> Mesh size was 130 mm square for cod, haddock an Pollock for ITQ fleet; <br> Minimum mesh size of 6 " was required for gillnets; <br> Minimum fish size is 43 cm (small fish protocols) for cod, haddock an Pollock for ITQ fleet; <br> OT>65' could not begin fishing until July 1; <br> Fixed gear must choose to fish either $5 Z$ or $4 X$ during June $1^{\text {st }}$ to September $30^{\text {th }}$. |
| 1995 | TAC $=1,000 \mathrm{mt}$ as a bycatch fishery; <br> January $1^{\text {st }}$ to June $18^{\text {th }}$ was closed to all groundfish fishery; <br> 130 mm square mesh size for all mobile fleets; <br> Small fish protocols continued; <br> $100 \%$ dock side monitoring; <br> Fixed gear vessels with a history since 1990 of 25 mt or more for 3 years of cod, Haddock, Pollock, hake or Cusk combined can participate in $5 Z$ fishery. |
| 1996 | TAC = 2,000 mt; <br> Prohibition of the landing of groundfish (except monkfish) by the scallop fishery; <br> ITQ vessel require minimum 130 mm square mesh for directed cod, Haddock and Pollock trips; <br> Small fish protocols continued; <br> For community management, quota allocation of each fixed gear based on catch history using the years 1986-1993; <br> $100 \%$ mandatory dockside monitoring and weighout. |
| 1997 | TAC $=3,000 \mathrm{mt}$ |
| 1998 | TAC $=1,900 \mathrm{mt}$ |
| 1999 | TAC = 1,800 mt; <br> Mandatory cod separator panel when no observer on board; January and February mobile gear winter Pollock fishery. |
| 2000 | TAC = 1,600 mt; <br> January and February mobile gear winter Pollock fishery. |
| 2001 | TAC $=2,100 \mathrm{mt}$ |
| 2002 | TAC $=1,192 \mathrm{mt}$ |
| 2003 | TAC $=1,301 \mathrm{mt}$ |

| Year | Canadian Management History |
| :---: | :---: |
| 2004 | TAC = 1,000 mt; <br> Canada-USA resource sharing agreement on Georges Bank. |
| 2005 | TAC = 740 mt ; Exploratory winter fishery January to February 18, 2005; Spawning protocol: $25 \%$ of maturity stages at 5 and 6 . |
| 2006 | TAC = 1,326 mt; Exploratory winter fishery January to February 6, 2006; Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2007 | TAC = 1,406 mt; Exploratory winter fishery January to February 15, 2007; High mobile gear observer coverage (99\%); Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2008 | TAC = 1,633 mt; <br> Winter fishery from January $1^{\text {st }}$ to February 8, 2009; <br> At-sea observer coverage $38 \%$ by weight of the mobile gear fleet landings and $21 \%$ by weight of the fixed gear landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2009 | $\mathrm{TAC}=1,173 \mathrm{mt} ;$ <br> Winter fishery from January 1 to February 21, 2009; <br> At-sea observer coverage $23 \%$ by weight of the mobile gear fleet landings and $15 \%$ by weight of the fixed gear landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2010 | TAC = 1,350 mt; <br> Winter fishery from January 1 to February 8, 2010; <br> At-sea observer coverage $18 \%$ by weight of the mobile gear fleet landings and $6 \%$ by weight of the fixed gear landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2011 | TAC = 1,050 mt; <br> Winter fishery from January 1 to Februay 5, 2011; <br> At-sea observer coverage $19 \%$ by weight of the mobile gear fleet landings, $20 \%$ by weight of the fixed gear landings and $3 \%$ by weight of the gillnet fleet landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2012 | $\text { TAC }=513 \mathrm{mt}$ <br> Winter fishery from January 1 to February 6, 2012; <br> At-sea observer coverage $42 \%$ by weight of the mobile gear fleet landings, $26 \%$ by weight of the fixed gear landings and $35 \%$ by weight of the gillnet fleet landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2013 | TAC = 504 mt ; <br> Winter fishery from January 1 to February 3, 2013; <br> At-sea observer coverage $78 \%$ by weight of the mobile gear fleet landings, $29 \%$ by weight of the fixed gear landings and $19 \%$ by weight of the gillnet fleet landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |

2b)

| Year | USA Management History |
| :---: | :---: |
|  | Regulatory Actions |
| 1953 | ICNAF era |
| 1973-1986 | TAC implemented for Div. 5Z cod; 35,000/year |
| 1977 | Groundfish Fishery Management Plan (FMP Magnuson-Steveson Conservation management Act (MSCMA) |
| 1982 | Interim FMP |
| 1984 | Hague Line implemented |
| 1985 | Multi-species FMP |
| 1989 | Amendment 2 |
| 1994 | Emergency Rule - December year-round closures in effect |
| 1994 | Amendment 5; Days at Sea (DAS) monitoring; Mandatory reporting; Vessel Trip Reports (VTR) Amendment 6 |
| 1996 | Amendment 7; accelerated DSA reduction Sustainable Fisheries Act (SFA) |
| 1999 | Amendment 9 |
| 2002 | Interim rule; 20\% reduction in DAS |
| 2004 | Amendment 13; further reduction in DAS; hard TAC on eastern Georges Bank haddock and cod Eastern US/CAN Area haddock Special Access Program (SAP) Pilot Program |
| 2005 | DAS vessels limited to one trip/month in eastern US/CAN Area until April $30^{\text {th }}$ Limited access DAS vessles required to use separator panel trawl in the area |
| 2006 | Haddock separator trawl or flounder net required in eastern US/CAN Area |
| 2008 | Eastern US/CAN Area access delayed until August ${ }^{\text {st }}$, except longline gear September - Ruhle trawl (eliminator trawl) allowed in eastern US/CAN Area |
| 2009 | November - Eastern US/CAN Area, trawl vessels required to use separator/Ruhle south 41-40N |
| 2010 | Amendment 16, Framework 44 implemented; Secotr management; Prohibition on discarding legal size fish US/CAN Area: prohibition on discarding legal size fish |
|  | Mesh Sizes (Inches) |
| 1953 | 4.5 |
| 1977 | 5.125 |
| 1983 | 5.5 |
| 1987 | 6.0 |
| 1989 | Eliminate 6 inch increase |
| 1994 | 6.0 |
| 1999 | 6.5 square mesh / 6.0 diamond mesh |
| 2000 | 6.5 square mesh / 6.5 diamond mesh |
| 2002 | 6.5 square mesh / 6.5 diamond mesh / 6.5 gill net |
|  | Minimum Size |
| 1977 | 16 inches ( 40.6 cm ) commercial and recreational |
| 1982 | 17 inches ( 43.2 cm ) commercial; 15 inches ( 38.1 cm ) recreational |
| 1986 | 19 inches ( 48.3 cm ) commercial; 17 inches ( 43.2 cm ) recreational |
| 1988 | 19 inches ( 48.3 cm ) commercial and recreational |
| 1997 | 21 inches (53.3) recreational |
| 2002 | 22 inches ( 55.9 cm ) commercial; 23 inches ( 58.4 cm ) recreational |
| 2003 | 21 inches ( 53.3 cm ) recreational |
| 2013 | 19 inches ( 48.3 cm ) commercial |
|  | Trip Limits |
| 2004 | Georges Bank cod: 2,000 lbs/day; 10,000 Ibs/trip; eastern Georges Bank: hard TAC on cod $500 \mathrm{lbs} /$ day; $5,000 \mathrm{lbs} /$ trip in eastern US/CAN Area |
| 2005 | $500 \mathrm{lbs} /$ day; $5,000 \mathrm{lbs} /$ trip in eastern UC/CAN Area Starting July, one trip/month in eastern US/CAN Area until April 30, 2006 |
| 2006 | $500 \mathrm{lbs} / \mathrm{day}$, 5,000 lbs/trip in eastern US/CAN Area |
| 2007 | $1,000 \mathrm{lbs} /$ trip of cod in eastern US/CAN Area or Haddock SAP |

| Year | USA Management History |
| :---: | :---: |
| 2008 | 1,000lbs/trip of cod in eastern US/CAN Area, fishing eastern Geoges Bank exclusively |
| 2009 | March - $500 \mathrm{lbs} /$ trip of cod in eastern US/CAN Area; back to 1,000 in April April $16^{\text {th }}$ - eastern US/CAN Area closed until May $1^{\text {st }}$ |
| 2010 | Georges Bank cod: 2,000 lbs/day; 20,000/trip; eastern Georges Bank cod: $500 \mathrm{lbs} / \mathrm{day}$, 5,000 lbs/trip |
| 2011 | March - 3,000 lbs/day during April $500 \mathrm{lbs} /$ day after April in eastern Georges Bank area |
|  | Closures |
| 1970 | Area 1(A) and 2(B) March-April |
| 1972-1974 | Area 1(A) and 2(B) March-May |
| 1977 | Seasonal spawning closure |
| 1987 | Modify Closed Area I to overlap with haddock spawning area |
| 1994 | January Closed Area II expanded, closed January -May, Closed Area I closed to all vessels except sink gillnet <br> December Closed Area I and II closed year-round to all vessels |
| 1999 | Scallopers allowed limited access to Closed Area II |
| 2004 | May to December access to northern corner of Closed Area II and adjacent area to target haddock with separator trawl <br> October - eastern Georges Bank closed to multi-species DAS permits |
| 2005 | January - eastern US/CAN Area reopened <br> April - eastern US/CAN Area closed until April $30^{\text {th }}$ <br> August - eastern US/CAN area closed (Georges Bank cod TAC projected near 90\%) |
| 2006 | Eastern US/CAN haddock SAP delayed opening until August $1^{\text {st }}$ |
| 2007 | April $25^{\text {th }}$ - eastern US/CAN Area closed until April $30^{\text {th }}$ <br> June - eastern US/CAN Area closed to limited access multi-species TAC (due to cod catch) <br> October - eastern US/CAN Area open to limited access multi-species TAC <br> November - eastern US/CAN Area closes |
| 2008 | May - eastern US/CAN Area delayed opening until August $1^{\text {st }}$, <br> June - eastern US/CAN Area delayed opening until August $1^{\text {st }}$ for all gear (prevent catching $1^{\text {st }}$ quarter cod TAC) |
| 2009 | May - eastern US/CAN Area closed until August ${ }^{\text {st }}$ for trawl vessels |
| 2010 | April - eastern US/CAN Area closed; May $1^{\text {st }}$ opening delayed untl August |

Table 15. Swept area biomass ( $m t$ ) for eastern Georges Bank cod from the DFO, NMFS spring and fall surveys. Conversion factors to account for vessel and trawl door changes have been applied, the biomass conversion factor used for the Henry B. Bigelow since 2009 is 1.58, the numbers in brackets show the unconverted values.

| Year | NMFS Fall |  | NMFS spring |  | DFO |

Table 26. Eastern Georges Bank Atlantic cod projected 2015 fishing mortality (F), 2016 January $1^{\text {st }}$ stock biomass (ages 3+), and percent increase in biomass from 2015 to 2016, based on 2015 projected catch at $F_{\text {ref }}=0.18$ and $F=0.11$ for each of two 'true state of nature' management models: VPA "M0.8" and ASAP $M=0.2$, and the consequence analysis of the projections of the alternative management action. Considering $F_{\text {ref }}=0.18$ is not consistent with the assessment VPA"M 0.8" model, it is inappropriate for the catch advice (shown in top left dark grey shaded box font).

## APPENDIX

## APPENDIX A. 2014 STATISTICAL CATCH AT AGE (ASAP) MODEL UPDATE FOR EASTERN GEORGES BANK ATLANTIC COD

## Introduction

This assessment presents an update of the statistical catch at age model 'Age Structured Assessment Program' (ASAP) reviewed at the 2013 April Eastern Georges Bank cod benchmark model meeting. The ASAP model was not chosen by the TRAC as a benchmark model for stock status or catch advice, however, the TRAC agreed to apply the ASAP model results in a consequence analysis (Appendix A) of projection results.
The ASAP model was chosen to explore as an alternative model to the virtual population model (VPA) during the EGB cod benchmark in part because ASAP had recently been accepted as the new benchmark model for the NEFSC GB cod assessment, replacing the VPA that had historically been applied since 1978 (NEFSC, 2013). Prior to 2004, both the EGB and GB cod assessments had been conducted with VPA and had similar formulations. After the 2002 EGB cod benchmark review (O'Boyle and Overholtz, 2002) the assessments started to diverge. While it is not mandatory that the two assessments be similarly formulated, given that EGB cod, a subcomponent of the Georges Bank stock, is managed by the Transboundary Management Guidance Committee (TMGC) and the whole stock is managed by the New England Fishery Management Council (NEFMC), similarly scaled biomass estimates would allow for compatibility in management decisions.
ASAP was used to derive estimates of instantaneous fishing mortality in 2013 and stock size in 2013. A retrospective analysis was performed for terminal year fishing mortality, spawning stock biomass, and age 1 recruitment. Stochastic projections from model results were performed to provide estimated landings and spawning stock biomass (SSB) in 2015-2016.

## Assessment Model Formulation

## Model Description

ASAP, a forward projecting statistical catch at age model (Legault and Restrepo 1998) can be downloaded from the NOAA Fisheries Toolbox (NFT, http://nft.nefsc.noaa.gov/). As described on the NFT website, ASAP is an age-structured model that uses forward computations assuming separability of fishing mortality into year and age components to estimate population sizes given observed catches, catch-at-age, and indices of abundance. Discards can be treated explicitly. The separability assumption is partially relaxed by allowing for fleet-specific computations and by allowing the selectivity at age to change in blocks of years. Weights are input for different components of the objective function which allows for configurations ranging from relatively simple age-structured production models to fully parameterized statistical catch at age models.

The objective function is the sum of the negative log-likelihood of the fit to various model components. Catch at age composition is modeled assuming a multinomial distribution. Surveys can be treated as either "west coast style" in the same manner as the catch data with a total survey time series and survey catch at age composition modeled assuming a multinomial distribution, or "east coast style" with the survey indices at age entered as separate series. Most other model components are assumed to have lognormal error. Specifically, lognormal error is assumed for: total catch in weight by fleet, survey indices, stock recruit relationship, and annual deviations in fishing mortality. Recruitment deviations are also assumed to follow a lognormal distribution, with annual deviations estimated as a bounded vector to force them to sum to zero
(this centers the predictions on the expected stock recruit relationship). For further details, the reader is referred to the technical manual (Legault 2008).

## Data Input

Input to the ASAP model is the same as the VPA and includes the total catch (mt) for the combined landings and discards of USA and Canadian fleets (main document - Table 1, Figure 2), and the catch-at-age (Table 5, Figure 12) and weight-at-age (Table 6, Figure 13) for ages 1-10+ during 1978-2013. Beginning year weight-at-age is back-calculated from the midyear catch weight-at-age (Table A1) and also estimated from an average of the DFO and NEFSC spring research survey weight-at-age (Table 16). Swept-area population estimates derived from indices of abundance include the Canadian DFO 1986-2013 estimates for ages 110+ (Table 9, Figure 19), the NEFSC 1978-2013 standardized spring estimates for ages 1-10+ (Table 10, Figure 19), and the NEFSC 1978-2013 standardized autumn estimates for ages 1-6 (Table 11, Figure 19). The NEFSC spring survey was dis-aggregated into two series based on the use of the Yankee \#41 otter trawl from 1978-1981 and the Yankee \#36 otter trawl from 1982-2008. The NEFSC surveys have been standardized to account for different vessels over the time series and for a change in trawl doors in 1985 (Table 7). The NEFSC surveys have been conducted by the NOAA ship Henry B. Bigelow since 2009 and these indices have been calibrated to former NOAA ship Albatross IV units (Table 8). No conversion factors are applied to the DFO survey indices. The maturity ogive was age and time invariant and knife edge maturity was assumed at age 3 as in previous EGB cod assessments. Natural mortality (M) was age and time invariant and assumed to be 0.2 as in earlier assessments (Wang and O'Brien, 2012).

## Model Formulation

The 2013 ASAP model formulation (base_rivard) presented and reviewed at the June 2013 TRAC (Wang and O'Brien, 2014) was updated for the 2014 assessment. A multinomial distribution was assumed for both fishery catch at age and survey age compositions. The catch $C V$ was set equal to 0.05 and the recruitment CV set equal to 0.5 , however, the recruitment deviations were set with lambda $=0$, so the deviations did not contribute to the objective function.

Both the fishery and survey selectivity was modeled as 'flat-topped'. For the fisheries, two selectivity blocks were modeled as single logistic from 1978-1993 and 1994-2013.

The effective samples size (ESS) of the catch and surveys were adjusted based on interpretation of 'lanelli' plots (McAllister and lanelli 1997). The input ESS is compared to the model predicted ESS; an appropriate ESS is considered to be that which intersects the input ESS.

The catch ESS was set at 75 for 1978-1995 and 125 for 1996-2013, and the ESS for each survey was set at 50 .
At the 2012 benchmark (WP 2013/08) the CV for each survey was initially set at the value generated from the survey estimate of stratified mean number per tow (DFO STRANAL). For the DFO survey the CVs averaged 0.31 , with a range of $0.15-0.66$, for the NEFSC spring the CVs averaged 0.32 , with a range of $0.13-0.83$, and for the NEFSC autumn survey the CVs averaged 0.47 , with a range of $0.24-0.88$. Further examination of the model fits to the survey indices resulted in adding the following constant to each survey CV vector: 0.25 (DFO), 0.3 (NEFSC spring \#36), and 0.2 (NEFSC autumn), except the NEFSC spring \#41, which was not adjusted. These same values were added during this 2014 update.

## Model Results

Model results, including the objective function (OF), components to the OF, the root mean square error (RMSE), computed from standardized residuals, SSB, fishing mortality (F), recruitment estimates at age 1, and the Mohn's rho retrospective bias adjustments are summarized in Table A2 for all model runs conducted.

A bridge ASAP run was conducted to include several corrections to the input data. A correction was made to the US catch at age (CAA) due to the misapplication of discard length frequencies. Last year, the January-June length frequency was erroneously applied to the July-December data.

Also, an adjustment was made to the DFO and NEFSC spring survey CAA due to the incorrect summation of the 10+ age group. And the 2012 NEFSC spring and 2011 autumn survey indices were re-estimated due to missing station data when first estimated using preliminary data in 2013.

A comparison of the differences between the 2013 ASAP model results (2013 run2) and the bridge run (2014 run1) resulted in an increase in the objective function (OF), and minor changes in age composition and root mean square errors (RMSE). There was a decline in estimates of recruitment and SSB, and an increase in fishing mortality (F) and the retrospective Mohn's rho estimate for SSB and F increased, whereas the recruitment rho estimate declined (Table A2).

BASE 2014 ASAP
The bridge run was updated with 2013 catch estimates and survey data and the results are described below.

#### Abstract

Catch The model fit to the observed catch is almost exact with the CV of 0.05 assigned to the commercial catch (Figure A1). The catch age composition exhibits larger residuals early in the time period, with a pattern of negative residuals for age 3 (Figure A2). The magnitude of the input ESS appears appropriate given that the predicted ESS generally bisects the observed ESS (Figure A3).

\section*{Indices}

The fit of the predicted indices through the observed DFO survey indices was better during the period 1995-2000 than before or after that period; in recent years the model fit does not bisect the survey confidence bounds for all years (Figure A4). A pattern of negative residuals in the older age groups during 1986-1995 and in the younger ages during 2000-2013 is apparent in the age composition (Figure A5). The final DFO survey ESS was set at 50 and appears appropriate given that the predicted ESS generally bisects the observed ESS (Figure A6).

The fit of the predicted indices through the NEFSC autumn survey indices did not show any strong patterning, although in recent years the model fit does not bisect the survey confidence bounds for all years (Figure A7). The maximum residual of the age composition is the largest of the 4 surveys at 0.36 (Figure A8). The age 1 residuals are large and have a positive values in the early years and a negative pattern in the later years, however, the older ages do not exhibit this pattern (Figure A8). The final input ESS was set = 50 and appears appropriate given that the predicted ESS generally bisects the observed ESS (Figure A9).

The model fit diagnostics for the NEFSC spring (Yankee \#41) are presented in Figures A10A12. With only 4 years of survey indices, no patterns are easily described or evaluated.

The fit of the predicted indices through the NEFSC spring (Yankee \#36) survey indices indicated, similar to the DFO survey, a series of negative residuals in the late 1980s to 1994 and a series of positive residuals since the mid-2000s (Figure A13). The residuals of the age
composition show a pattern of positive residuals in age 2 and negative in age 4 in the early years and the opposite in the later years (Figure A14). The input ESS was set = 50 and appears appropriate given that the predicted ESS generally bisects the observed ESS (Figure A15).

## Fishing Mortality, SSB, and Recruitment

Fully recruited F (unweighted, ages 5+) was estimated at 0.33 in 2013 (Table 3A and Figure A16), a 59\% decrease from 2012. SSB in 2013 was estimated at 2,142 mt, a 80\% increase from 2012 (Table A3 and Figure A16). Recruitment (millions of age 1 fish) of the 2003 year class ( 2.4 million) is now estimated to be smaller than the 1998 year class ( 3.4 million), the 2010 year class is estimated at 1.5 million, and the 2012 year class is the smallest year class estimated at 0.125 million (Table A3 and Figures A16-A17).

## Retrospective Analysis

A retrospective analysis was performed to evaluate how well the ASAP calibration would have estimated F, SSB, and recruits at age 1 for seven years (2006-2012) prior to the terminal year, 2013. The pattern of overestimating SSB and underestimating $F$ relative to the terminal year
is stronger than in the 2013 ASAP model (Wang and O'Brien, 2013), and there is a pattern of underestimating recruitment relative to the terminal year estimate (Figure A18). The retrospective rho values, the average of the last 7 years of the relative retrospective peels, were 0.46 for SSB, -0.32 for $\mathrm{F}_{5+}$, and -0.25 for recruitment. Applying a retrospective adjustment $((1 /(1+\mathrm{rho}))$ * estimate) results in estimates for 2013 of $\mathrm{F}=0.49, \mathrm{SSB}=1,470 \mathrm{mt}$, age 1 recruitment $=0.17$ million fish.

## Model Uncertainty - Monte Carlo Markov Chain (MCMC)

A Monte Carlo Markov chain (MCMC) simulation was performed to estimate uncertainty in the model estimates. The MCMC provides posterior probability distributions of the SSB and average F5+ time series. Two MCMC chains of initial length of 5.0 million were simulated with every 2,500 th value saved. The trace of each chain's saved draws suggests good mixing for both SSB and $F$ (Figure A19). The lagged autocorrelations showed variable correlation with increased lag, with correlations $\leq 0.1$ beyond lag 0 for SSB and F (Figure A200). From the MCMC distributions, a $90 \%$ probability interval ( PI ) was calculated to provide a measure of uncertainty for the model point estimates for SSB and average F5+. Time series plots of the $90 \%$ PIs as well as plots of the posterior probability distributions for SSB2012 and average F5+ are shown in Figures A21-A22.

The 2013 SSB MCMC estimate of $2,134 \mathrm{mt}$ has a $90 \%$ PI of $1,384 \mathrm{mt}-3,345 \mathrm{mt}$ and the 2013 MCMC average $\mathrm{F} 5+=0.33$ has a $90 \% \mathrm{PI}$ of $0.20-0.56$.

## Sensitivity Runs

The base ASAP model was run using Jan. 1 back-calculated mean weight at age based on the Rivard method (Rivard, 1982). A sensitivity run was done using Jan. 1 weight at age based on an average of the DFO and NMFS spring survey data as applied in the VPA. The results (Table A2) indicate minimal differences when applying these two weight-at-age matrices. The base run with rivard weights will be used in projections, as this follows the weight at age used for the GB cod assessement (NEFSC, 2013b).
Various other sensitivity runs were conducted, but none showed substantial improvements in model diagnostics.

## Biological Reference Points

## Yield per Recruit Analysis

For the 2013 EGB cod model benchmark meeting, a yield per recruit (YPR) analysis was conducted using the methods of Thompson and Bell (1934). Input data for catch and stock weights (ages 1-10+) were derived from an average of the most recent five years (2007-2011). The partial recruitment (PR) was based on a normalized arithmetic mean of 2007-2011 total fishing mortality from the ASAP model run3f.1. The maturity ogive was knife-edge at age 3. Results of YPR analysis are presented below. The current negotiated EGB cod F reference point is $F_{\text {ref }}=0.18$ (TMGC meeting December 2002). (The current GB cod $\mathrm{F}_{\text {MSY }}$ proxy $=$ $\mathrm{F}_{40 \%}=0.18$ ).

|  | F |
| :--- | ---: |
| F0.1 | 0.19 |
| fmax | 0.43 |
| F30\% | 0.29 |
| F40\% | 0.19 |
| Fcurrent | 0.45 |

EGB cod is not managed by biomass reference points, however, for background purposes, nonparametric estimates of MSY and SSBMSY based on F40\% were estimated using the 34-year time series mean recruitment (5.484 million age 1 fish), Y/R (1.22) and SSB/R (7.18) as:

- $\mathrm{F}_{40 \%}=0.19$,
- $\mathrm{MSY}=6,677 \mathrm{mt}$, and
- $\mathrm{SSB}_{\text {msy }}=39,353 \mathrm{mt}$.

The yield per recruit analysis was not updated with the 2014 June ASAP results.

## MSY Biological Reference Points

## Long-term Stochastic Projection

For the 2013 EGB cod model benchmark meeting, long term (100 years) stochastic projections were run using the same input data as the YPR with $F_{\text {ref }}=0.18$. Following the NEFSC GB cod accepted assessment projection formulation (NEFSC, 2013), recruitment was estimated from a 2 stage cumulative distribution function (CDF) based on either 19 low estimates or 14 high estimates of age 1 recruitment. Based on a visual examination of the stock recruit plot (Figure A17), when SSB is $<15,000 \mathrm{mt}$ recruitment is drawn from the low recruitment CDF, and when SSB $>15,000 \mathrm{mt}$ then recruitment is drawn from the high recruitment CDF.

The long term projection provided the following non-parametric biomass reference points:

- $F_{\text {ref }}=0.18$,
- $\quad$ MSY $=11,059 \mathrm{mt}(80 \% \mathrm{CI}: 2,065 \mathrm{mt}-14,180 \mathrm{mt})$, and
- $\mathrm{SSB}_{\text {msy }}=30,622 \mathrm{mt}(80 \% \mathrm{Cl}: 25,450 \mathrm{mt}-84,346 \mathrm{mt}$ ).

## Projections

Short term stochastic projections under $\mathrm{F}_{40 \%}$ were performed from the updated 2014 ASAP model results to estimate landings and SSB during 2015-2016. The input values for mean catch and stock weights, partial recruitment (PR), and maturity were estimated as 3-year averages from 2011-2013. Recruitment was estimated using the 2 -stage CDF described above and associated with a SSB breakpoint of $15,000 \mathrm{mt}$. Catch in 2014 was estimated based on the assumption that the 2013 quota of 700 mt would be caught.

The results of the short term projections indicate under the $\mathrm{F}_{\text {ref }}=0.18$ catch is projected to decrease in 2015 then increase in 2016, and similarly, SSB is projected to decrease in 2015, then increase in 2016.

| Year | SSB | F | Catch |
| ---: | ---: | ---: | ---: |
| 2014 | 2914 | 0.32 | 700 |
| 2015 | 2820 | 0.18 | 489 |
| 2016 | 3283 | 0.18 | 525 |

## Summary Discussion

Productivity of EGB has been low for the last two decades with poor recruitment and truncated age structure. An increase in natural mortality may have contributed to the recent low productivity, however, food habits data do not support this hypothesis (NEFSC, 2013b). Analysis of tagging data indicates minimal increase in M from the 1980s to the 2000s, and thus does not appear sufficient to explain the long term low productivity (Miller, WP $2^{1}$ ). Lack of large numbers of older repeat spawners in the EGB cod population since the mid-1980s may contribute to the long-term low productivity. Cod have a low success rate of hatching for first and second time spawners ( $13 \%$ and $62 \%$ ) until the third spawning (100\%), suggesting that an expanded age structure of fish that have spawned 3 or more times would contribute to higher productivity (Trippel, 1998). Long-term overfishing may have also had indirect effects. Fishing activity disrupts the spawning aggregation and thus behaviors and rituals of cod, reducing the potential of good recruitment (Dean, 2012). Spawning of cod involves complex behaviors that have only recently been observed including arrival and departure of fish on the spawning ground at different times dependent upon sex, age, and stage of maturity (Lawson and Rose, 2000) and the formation of spawning leks, where the males set up and defend territory (Windle and Rose, 2007).
The updated model formulation exhibits an increase in the retrospective bias in F and SSB compared to the 2013 ASAP model results. In the ASAP formulation, additional variability is added to the survey abundance estimates, thus placing more emphasis on the reported catch data.

## Appendix A - Figures

Figure A1. ASAP model fit to total catch of eastern Georges Bank cod, 1978-2013.

Figure A2. ASAP model residuals for the commercial catch age composition of eastern Georges Bank cod, 1978-2013.

Figure A3. ASAP model observed (line) and predicted (circles) effective sample size of eastern Georges Bank cod in the total catch, 1978-2013.

Figure A4. ASAP model fit to DFO survey indices of eastern Georges Bank cod, 1986-2013.

Figure A5. ASAP model run age composition residuals for DFO survey index of eastern Georges Bank cod, 1986-2013.

Figure A6. ASAP model observed (line) and predicted (circles) effective sample size of eastern Georges Bank cod in the DFO survey, 1986-2013.

Figure A7. ASAP model fit to NEFSC autumn survey indices of eastern Georges Bank cod, 1978-2013.

Figure A8. ASAP model age composition residuals for NEFSC autumn survey index of eastern Georges Bank cod, 1978-2013.

Figure A9. ASAP model observed (line) and predicted (circles) effective sample size of eastern Georges Bank cod in the NEFSC autumn survey, 1978-2013.

Figure A10. ASAP model fit to NEFSC spring Yankee \#41 trawl survey indices of eastern Georges Bank cod, 1978-1981.

Figure A11. ASAP model age composition residuals for NEFSC spring Yankee \#41 trawl survey index of eastern Georges Bank cod, 1978-1981.

Figure A12. ASAP model observed (line) and predicted (circles) effective sample size of eastern Georges Bank cod in the NEFSC spring Yankee \#41 trawl survey, 1978-1981.

Figure A13. ASAP model fit to NEFSC spring Yankee \#36 trawl survey indices of eastern Georges Bank cod, 1982-2013.

Figure A14. ASAP model age composition residuals for NEFSC spring Yankee \#36 trawl survey index of eastern Georges Bank cod, 1982-2013.

Figure A15. ASAP model observed (line) and predicted (circles) effective sample size of eastern Georges Bank cod in the NEFSC spring Yankee \#36 trawl survey, 1982-2013.

Figure A16. ASAP model results for fishing mortality (ages 5+), spawning stock biomass, and recruitment (age1; 000s fish), 1978-2013.

Figure A17. ASAP model results (left panel) for spawning stock biomass (mt, line) and recruitment (age1; 000s fish, bars) and the stock - recruitment plot ( right panel) with year-class designation, 1978-2013.

Figure A18. ASAP model results of retrospective bias of fishing mortality ( $F$ ), spawning stock biomass (SSB), and age1 recruitment. Retrospective bias adjustment for $F=-0.32, S S B=0.46$, and age 1 recruitment $=-0.25$.

Figure A19. ASAP model results of trace of MCMC chains for eastern Georges Bank cod fishing mortality (left) and spawning stock biomass (right) for 1978 and 2013. Each chain had an initial length of 5.0 million and was thinned at a rate of one out of every $2,500^{\text {th }}$ resulting in a final chain length of 2000.

Figure A20. ASAP model autocorrection within the 1978 and 2013 MCMC chains for fishing mortality (F, left panel) and spawning stock biomass (SSB, right panel) for eastern Georges Bank cod.

Figure A21. ASAP model 90\% probability interval for eastern Georges Bank fishing mortality (left) and cod spawning stock biomass (SSB). The median value is in red, while the $5^{\text {th }}$ and $95^{\text {th }}$ percentiles are in dark grey. The point estimate from the model (joint posterior modes) is shown in the thin green line with filled triangles.

Figure A22. ASAP model MCMC distribution of eastern Georges Bank and fishing mortality (F, left panel) and cod spawning stock biomass (SSB, right panel) in 1978 and 2013. The model point estimate is indicated by the dashed red line.
