#### Abstract

The total catch of eastern Georges Bank (EGB) haddock in 2014 was $14,243 \mathrm{mt}$ of the 27,000 mt combined Canada/United States of America (USA) quota. The 2014 Canadian catch increased from 4,631 mt in 2013 to 12,936 mt while the USA catch in 2014 was 1,182 mt , an increase from the 2013 catch of 435 mt . Haddock discards from the Canadian scallop fishery and the USA groundfish fishery were estimated at 17 mt and 108 mt , respectively.

The 2015 beginning of year adult population biomass (ages $3+$ ) is estimated at $117,000 \mathrm{mt}$. A preliminary estimate for the 2014 year class is 12.9 million fish at age 1 . The current estimate of the 2013 year class is 1,300 million fish, which is the highest in the time series (1931-1955 and 1969-2014). The exceptional 2003 and 2010 year classes, estimated at 210 million and 275 million age 1 fish, respectively, are the second and third largest. Except for the strong 2000 and 2011 year classes, and the exceptional 2003, 2010 and 2013 year classes, recruitment has fluctuated between 2.1-27.3 million fish since 1990. Fully-recruited fishing mortality increased to levels above $F_{\text {ref }}=0.26$ from 2010-2012 before dropping off again in 2013. In 2014, $F$ was estimated at 0.23 . Positive signs of productivity include expanded age structure, broad spatial distribution, large biomass and three exceptional year classes and two strong year classes since 2000. On the negative side, condition has decreased substantially and size at age has declined.

Assuming a 2015 catch equal to the $37,000 \mathrm{mt}$ total quota and $\mathrm{F}=0.26\left(\mathrm{~F}_{\text {ref }}\right)$ in 2016 and 2017, a combined Canada/USA catch of $37,500 \mathrm{mt}$ in 2016 results in a neutral risk (50\%) that the 2016 fishing mortality rate would exceed $F_{\text {ref }}=0.26$. The 2010 year class at age 6 is expected to contribute $46 \%$ of the catch biomass and the 2013 year class at age 3 is expected to contribute the next highest percentage at $41 \%$. The probability that the 2017 biomass will not increase by $10 \%$ is negligible. Adult biomass is projected to be $522,000 \mathrm{mt}$ at the beginning of 2017 at the $F_{\text {ref }}$ catch level. A combined Canada/USA catch of $81,000 \mathrm{mt}$ in 2017 results in a neutral risk (50\%) that the 2017 fishing mortality rate would exceed $F_{\text {ref }}=0.26$. The 2010 year class at age 7 is expected to contribute $16 \%$ of the catch biomass and the 2013 year class at age 4 is expected to contribute $78 \%$. The probability that the 2018 biomass will not increase by $10 \%$ is high because population biomass is expected to decline from 2017 to 2018. Adult biomass is projected to be $464,000 \mathrm{mt}$ at the beginning of 2018 at the $\mathrm{F}_{\text {ref }}$ catch level.
Retrospective analyses indicated that the benchmark model has a tendency to underestimate $F$ and overestimate biomass and age 1 recruitment when additional years of data are added. To account for the retrospective bias, a sensitivity forecast using the rho adjusted 2015 population numbers (ages 0-9+) for deterministic projections and risk assessments was conducted to beginning year 2018. Assuming a 2015 catch equal to the $37,000 \mathrm{mt}$ total quota and $\mathrm{F}=0.26$ ( $F_{\text {ret }}$ ) in 2016 and 2017, a combined Canada/USA catch of 19,500 mt in 2016 results in a neutral risk (50\%) that the 2016 fishing mortality rate would exceed $\mathrm{F}_{\text {ref }}=0.26$. A combined Canada/USA catch of 45,000 mt in 2017 results in a neutral risk (50\%) that the 2017 fishing mortality rate would exceed $\mathrm{F}_{\text {ref }}=0.26$.
The $F_{\text {ref }}$ catches from the sensitivity projections are considerably lower than the catches from standard projections, but they do take into account the emerging retrospective pattern that has occurred over the past two years in this assessment.

## RÉSUMÉ

Le total des prises d'aiglefin dans l'est du banc Georges s'est élevé à 14243 tm en 2014, sur un quota combiné de 27000 tm pour le Canada et les États-Unis. Les prises canadiennes sont passées de 4631 tm en 2013 à 12936 tm en 2014, tandis que les prises américaines sont passées de 435 tm en 2013 à 1182 tm en 2014. On estime les rejets d'aiglefins dans la pêche canadienne du pétoncle et dans la pêche du poisson de fond aux États-Unis à 17 tm et 108 tm respectivement.
On estime qu'au début de l'année 2015, la biomasse de la population adulte (âges 3+) s'élevait à 117000 tm . L'estimation préliminaire pour la classe d'âge 2014 est de 12,9 millions de poissons d'âge 1. On estime actuellement la classe d'âge de 2013 à 1300 millions de poissons, ce qui en fait la cohorte la plus abondante des séries chronologiques 1931-1955 et 1969-2014. Les classes d'âge exceptionnelles 2003 et 2010, estimées à 210 millions et 275 millions de poissons d'âge 1, respectivement, sont les deuxième et troisième plus importantes. Sauf pour les fortes classes d'âge de 2000 et 2011 et les classes d'âge exceptionnelles de 2003, 2010 et 2013, le recrutement a fluctué entre 2,1 et 27,3 millions d'individus depuis 1990. La mortalité par pêche des poissons pleinement recrutés a augmenté à des niveaux dépassant $F_{\text {rét }}=0,26$ de 2010 à 2012, avant de baisser de nouveau en 2013. En 2014, la mortalité par pêche ( $F$ ) était évaluée à 0,23 . Parmi les signes encourageants de productivité, il y a l'élargissement de la structure par âge, la vaste répartition spatiale, la biomasse élevée, trois classes d'âge exceptionnelles et deux fortes classes d'âge depuis 2000. Parmi les signes négatifs, on note une détérioration importante de la condition et une diminution de la taille selon l'âge.
En supposant que les captures en 2015 soient égales au quota total de 37000 tm et que $F$ soit égale à 0,26 ( $\mathrm{F}_{\text {rét }}$ ) en 2016 et 2017, des prises combinées du Canada et des États-Unis s'élevant à 37500 tm en 2016 se traduiraient par un risque neutre ( $50 \%$ ) que le taux de mortalité par pêche dépasse $F_{\text {reff }}=0,26$ pendant cette année. La classe d'âge de 2010 à l'âge 6 devrait constituer 46 \% de la biomasse des prises et la classe d'âge de 2013 à l'âge 3 devrait constituer le deuxième plus haut pourcentage de la biomasse des prises avec $41 \%$ de celle-ci. La probabilité que la biomasse n'augmentera pas de $10 \%$ en 2017 est négligeable. On prévoit qu'au début de 2017, en tenant compte d'une capture de Fréf, $^{\text {l }}$ la biomasse des adultes sera de 522000 tm . Un total des prises combinées du Canada et des États-Unis de 81000 tm en 2017 se traduirait par un risque neutre ( $50 \%$ ) que le taux de mortalité par pêche dépasse $\mathrm{F}_{\text {réf. }}=$ 0,26 cette année-là. La classe d'âge de 2010 à l'âge 7 devrait constituer $16 \%$ de la biomasse des prises et la classe d'âge de 2013 à l'âge 4 devrait représenter $78 \%$ de celle-ci. La probabilité que la biomasse n'augmentera pas de $10 \%$ en 2018 est élevée, parce qu'on s'attend à ce que la biomasse de la population baisse de 2017 à 2018. On prévoit qu'au début de 2018, en tenant compte d'un niveau de prises situé à $F_{\text {réf, }}$ la biomasse des adultes sera de 464000 tm .

Des analyses rétrospectives ont indiqué que le modèle de référence a tendance à sous-estimer F et à surestimer la biomasse et le recrutement à l'âge 1 lorsque des années de données supplémentaires sont ajoutées. Pour tenir compte du biais rétrospectif, une prévision de sensibilité utilisant une correction rho des populations de 2015 (âges 0-9+) pour les projections déterministes et les évaluations des risques a été effectuée pour le début de l'année 2018. En supposant que les captures en 2015 soient égales au quota total de 37000 tm et que F soit égale à 0,26 ( $\mathrm{F}_{\text {rét }}$ ) en 2016 et 2017, des prises combinées du Canada et des États-Unis s'élevant à 19500 tm en 2016 se traduiraient par un risque neutre ( $50 \%$ ) que le taux de mortalité par pêche dépasse $F_{\text {réf }}=0,26$ pendant cette année. Un total des prises combinées du Canada et des États-Unis de 45000 tm en 2017 se traduirait par un risque neutre ( $50 \%$ ) que le taux de mortalité par pêche dépasse $F_{\text {réf. }}=0,26$ pendant cette année.

Les prises prévues à Frét établies par les projections de sensibilité sont très inférieures aux prises établies par les projections standard, mais elles tiennent compte de la tendance
rétrospective émergente qui a été observée au cours des deux dernières années de la présente évaluation.

## INTRODUCTION

For the purpose of developing a sharing proposal and consistent management by Canada and the United States of America (USA), an agreement was reached that the transboundary management unit for haddock would be limited to the eastern portion of Georges Bank (EGB; DFO statistical unit areas j and m in NAFO Subdivision 5Ze; USA statistical areas 551, 552, 561 and 562 in NAFO Subdivision 5Ze; DFO 2002; Figure 1). This assessment applies the approach used by Van Eeckhaute and Brooks (2014) to Canadian and USA fisheries information updated to 2014. Results from the Fisheries and Oceans Canada (DFO) survey, updated to 2015, the USA National Marine Fisheries Service (NMFS) spring survey updated to 2015, and the NMFS fall survey updated to 2014 were also incorporated. The NMFS surveys since 2009, which use a new vessel (NOAA ship Henry B. Bigelow), a new net and protocols, were made equivalent to surveys undertaken by the former NOAA ship Albatross IV by applying length-based conversion factors (Brooks et al. 2010).

## FISHERY

## COMMERCIAL CATCHES

Haddock on Georges Bank have supported a commercial fishery since the early-1920s (Schuck 1951; Clark et al. 1982). Catches from EGB during the 1930s to 1950 s ranged between 17,000$41,000 \mathrm{mt}$ (Figure 2). Records of catches by unit area for 1956 to 1968 are not available; however, based on records for NAFO Subdivision 5Ze, catches from EGB probably attained record high levels of about 60,000 mt during the early-1960s. Catches during the late-1970s and early-1980s reached a maximum of $23,344 \mathrm{mt}$, and were associated with good recruitment (Table 1; Figure 3). Substantial quantities of small fish were discarded in those years (Overholtz et al. 1983). Catches subsequently declined, fluctuating around $5,000 \mathrm{mt}$ during the mid- to late1980s. Under restrictive management measures (Table 2), combined Canada/USA catches declined from $6,504 \mathrm{mt}$ in 1991 to a low of $2,150 \mathrm{mt}$ in 1995, varied between $3,000-4,000 \mathrm{mt}$ until 1999, and increased to $15,256 \mathrm{mt}$ in 2005. Catches varied between $12,510 \mathrm{mt}$ and $19,855 \mathrm{mt}$ from 2006 to 2011 then decreased to $5,066 \mathrm{mt}$ in 2013. In 2014, the total catch increased to $14,243 \mathrm{mt}$ and represented $53 \%$ of the combined $27,000 \mathrm{mt}$ quota. Canada caught $79 \%$ of its $16,470 \mathrm{mt}$ allocation while the USA caught $12 \%$ of its $10,530 \mathrm{mt}$ allocation.

## Canadian

Some elements of the management measures used on EGB are described in Table 2. Quotas are the principal means used to regulate the Canadian groundfish fisheries on Georges Bank. Quota regulation requires effective monitoring of fishery catch. Weights of all Canadian landings since 1992 have been monitored at dockside. Canadian catches since 1995 have usually been below the quota due to closure of some fleet sectors when the cod quotas were reached. In 2014, at-sea observer coverage represented 64\% of otter trawl (OTB) and 38\% of longline landings, which amounted to an overall observed level of 64\% of haddock landings for the Canadian fishery. For OTB, coverage was 100\% from January to August and 25\% from September to December.

Between 1994 and 2004, the Canadian fishery for groundfish on EGB was closed from January $1^{\text {st }}$ to May $30^{\text {th }}$. In 2005, increasing haddock abundance led to authorization to conduct an exploratory Canadian groundfish fishery in January and February that has continued since that time. Observer coverage for this fishery has been higher than at other times of the year (i.e. 100\% in 2014). So as not to adversely affect the rebuilding of cod on EGB, the winter fishery was closed February $3^{\text {rd }}$ in 2014 based on determinations of active cod spawning in the
previous year (i.e. when $30 \%$ of cod were in "spawning" or "post-spawning" stages based on analysis of maturity data collected by observers).

The mandatory use of 130 mm square mesh cod ends for bottom trawls was implemented in 1995 to allow for escapement of smaller haddock, and has been the only mesh size used up until 2014 when the mobile gear sector was allowed to experiment with the use of 145 mm diamond mesh cod ends to improve catch rates in the winter fishery. This request was based on the reduced size at age of the extremely large 2010 year class and industry concerns about the increased effort and cost required to obtain good catches. The experimental gear ( 145 mm square mesh) was used during the winter fishery in a comparative study of retained haddock size composition with the standard 130 mm square mesh (note: for this study there was $100 \%$ observer coverage and mandatory use of separator panels to reduce cod bycatch). A further study was conducted by industry from June through August, 2014, to compare catch size composition between trawls using 145 mm diamond, 125 mm square and 130 mm square mesh. Industry was allowed to continue using the 145 mm diamond mesh until the fishery closed in December. All vessels operating from June-December were required to use bottom trawls equipped with separator panels regardless of the mesh size used. Based on the total number of observed sets in $2014(n=2169)$, the breakdown by mesh size was: 125 mm square: $5 \%, 130 \mathrm{~mm}$ square: $37 \%$ and 145 mm diamond: $58 \%$. Results of these studies were analyzed and documented in a summary report presented at the 2015 TRAC assessment meeting (see: Brooks and Curran 2015).

## Canadian Landings

Canadian landings increased from 4,631 mt in 2013 to $12,953 \mathrm{mt}$ in 2014, the highest since 2011. In recent years, the Canadian fishery has been conducted primarily by small OTB (i.e. Tonnage Classes (TC) 1-3, <150 mt) followed by longline, with minimal landings by gillnet (Table 3). The percentage of landings taken by longline has steadily declined since 1992 whereas the small OTB share has increased (Figure 4). Over the past 10 years, small OTB have taken an average of about $86 \%$ of the catch and longline vessels about $13 \%$. There has been a declining trend in longline catches since 2012, with the 2014 catch representing only $1 \%$ of total landings, and is attributed to the difficulties in avoiding cod bycatch. Large OTB (TC 4+) contributed $40-80 \%$ of total landings in the 1970s, although there are few left in the fishery at present (their contribution is currently <1\%). In 2014, the highest landings occurred in August, with highest percentage of total Canadian landings occurring in Quarter 3 (41\%) (Table 4; Figure 5). The 2014 January/February winter fishery landed 2,133 mt of haddock, accounting for $16 \%$ of total Canadian landings.

## Canadian Discards

Before 1996, Canadian landings included haddock catches reported by the scallop fishery. Landings of haddock by the scallop fleet were low (Table 3) with a maximum of 38 mt reported in 1987. Since 1996, the scallop fishery has been prohibited from landing haddock and so this species is discarded. Haddock discards from the scallop fleet have ranged between 10 mt and 186 mt since 1969 (Table 1). A 3-month moving window was used to calculate the discard rate and included December of the previous year for the January discard rate and January of the following year for the December rate (Van Eeckhaute et al. 2011). Discards from 2005 onward have been recalculated to reflect a change in the effort measure used (i.e. from freezer trawler hours to hours x metres; Sameoto et al. 2013). The effect on haddock discards was minimal. In 2014 there were 24 observed scallop trips available for calculating discards which were estimated at 17 mt , higher than the 10 mt reported in 2013 (Table 5).
Compliance with mandatory retention is thought to be high since 1992, so haddock discards in the groundfish fishery are considered to be negligible. The mandatory use of separator panels
for bottom trawls was implemented in 1999 to help reduce the bycatch of cod. Currently, all vessels in the fleet are using separator panels.

## USA

Management measures for the USA fishery have been primarily effort based since 1994; however, in 2004, quota management was introduced to regulate the USA groundfish fishery for EGB haddock (Table 2). From 2008 to 2010, the USA portion of the EGB management area was closed to vessels fishing with trawl gear from May $1^{\text {st }}$ to July $31^{\text {st }}$. From 2011 onwards, the regulation only applies to the common pool which is a miniscule fraction of USA boats that fish on EGB (the common pool received $0.62 \%, 0.28 \%$, and $0.32 \%$ of the EGB haddock quota in 2011, 2012, and 2013, respectively).

The minimum size for landed haddock had been reduced to 18 inches ( 45.7 cm ) in October 2007 but reverted back to 19 inches ( 48.2 cm ) in August 2008. On May 1, 2009, the minimum size was again reduced to 18 inches through a NMFS interim action. This minimum size limit was retained in Amendment 16, which went into effect on May 1, 2010. On September 15, 2008, the Ruhle Trawl (previously called the Eliminator Trawl) was authorized for use in the USA portion of EGB haddock management area. The Ruhle Trawl is intended to reduce bycatch of cod. Also, beginning on May 1, 2010, many participants in the multispecies groundfish fishery organized into sectors, with each unique sector receiving a portion of the overall quota known as an Annual Catch Entitlement (ACE). Those vessels not joining a sector remained in the common pool, which received a portion of the overall quota. A discard provision went into effect on May 1, 2010 requiring that all legal sized fish be retained by vessels in a sector. On May 11, 2011, the Closed Area II Special Access Permit (SAP) was modified to allow targeting of haddock from August $1^{\text {st }}$ to January $31^{\text {st }}$. Also, on September 14, 2011, the haddock catch cap regulation for the herring midwater trawl fishery increased to $1 \%$ of the Georges Bank Annual Biological Catch (ABC). Beginning July 1, 2013, the minimum size was reduced from 18 inches to 16 inches ( 40.64 cm ).

## USA Landings

USA landings of EGB haddock in 2014 were derived from mandatory fishing vessel trip reports (VTRs) and dealer reports. Statistical methodology was applied to allocate unknown landings to statistical area from 1994 to 2014 (Wigley et al. 2008a; Palmer 2008). Some of the landings for trawl gear that were reported in 2008 to 2010, during the months when EGB was closed to trawl gear, come from the allocation algorithm which assigns a statistical area when area is missing or there are inconsistencies in reported areas on logbooks. Trawl landings that were allocated to EGB during May to July for 2008-2010 comprised 3\% to 5\% of total annual USA landings.
USA calendar year landings (Table 1) of EGB haddock increased from 344 mt in 2013 to $1,182 \mathrm{mt}$ in 2014. The 2014 USA landings peaked in quarter 2 (44\%), primarily due to high landings in June, which represented $25 \%$ of total annual landings (Table 6). As in other years, otter trawl gear accounted for nearly all of USA landings (1,181 mt; Table 7), $76 \%$ of which was landed by tonnage class 4 vessels.
For USA fishing year May 1, 2014, to April 30, 2015, the USA catch quota for sectors was $10,005 \mathrm{mt}$ of which only $14.6 \%$ was realized in landings ( $15.4 \%$ of quota, including discards). The catch quota for the common pool was 69.1 mt , none of which was caught. In recent years, landings have been constrained in part by the low cod quota, the closed area, as well as the delayed opening of the EGB area to trawlers until August 1 ${ }^{\text {st }}$, in effect from 2008 to 2010 for all USA trawl gear and, since 2011, for the common pool only. The use of the Ruhle and Separator trawls may have reduced interactions with the cod quota.

## USA Discards

Discards were estimated from the ratio of discarded haddock to kept of all species, a new methodology that was first applied for the 2009 EGB haddock assessment. This ratio is calculated by year, quarter (or other suitable time step), gear and mesh type, and prorated to the total landings of all species in the same time-gear category to obtain total discards (mt) (Wigley et al. 2008b). Where time steps within the year are sparse, imputation is carried out.
Total discards in 2014 were 108 mt, an increase from 91 mt in 2013 (Table 1). Discards were slightly greater during the first half of the year (53\%). USA discards from the OTB fishery increased slightly from 87 mt in 2013 to 105 mt in 2014 accounting for $8.2 \%$ (by weight) of the USA haddock catch in 2014. Large mesh OTB discards were 66 mt , compared to 38 mt for small mesh OTB. Discards from the large mesh OTB were primarily from vessels using a separator trawl ( 55 mt ), with only 12 mt of discards due to standard trawl gear. The scallop fishery contributed a very small amount of discards in $2014(2.9 \mathrm{mt})$ as did lobster pots ( 0.3 mt ).

## SIZE AND AGE COMPOSITION

## Ageing Precision and Accuracy

D. Knox provided ages for the 2014 Canadian fishery and 2015 DFO survey and
S.J. Sutherland provided ages for the 2014 US fishery and the NMFS 2014 fall and 2015 spring surveys. Age testing was conducted between the DFO reader and the NMFS reader and intrareader testing was conducted at both labs (Table 8; http://www.nefsc.noaa.gov/fbp/QA-QC/hdresults.html). The NMFS reader also completed a test against the haddock reference collection, which resulted in $93 \%$ agreement. Inter-lab agreement ranged from $72 \%$ to $94 \%$. No bias was detected for the exchange. Intra-reader agreement on non-reference collection samples for the NMFS reader ranged between $92 \%$ and $100 \%$. For the DFO reader, intra-reader agreement ranged between $88 \%$ and $98 \%$. Age determinations at both labs were considered to be reliable for characterizing catch at age.

## Canadian

The size and age composition of haddock in the 2014 Canadian groundfish fishery was determined using port and at-sea samples from all principal gears with 496,341 length measurements and 1,287 ages available to characterize the catch (Table 9). For trips that were sampled by both at-sea observers and port samples, the length frequencies from the two sources were combined with appropriate weighting from each source to ensure that samples were used in a consistent manner. Examination of the quarterly size composition of haddock sampled at sea from bottom trawls using different cod end mesh sizes/types (i.e. 145 mm diamond mesh, 125 mm and 130 mm square mesh) indicated that all three cod ends generally retained similar sizes of fish (Figure 6). Although some seasonal differences were apparent in the size composition of haddock captured using 125 mm square mesh, very few trips actually used this cod end in the 2014 fishery. Therefore, it was not considered necessary to separate out the haddock length and age samples from all three mesh types for catch at age (CAA) calculations. Gillnet landings were low and no length samples were available; these landings were added in at the quarter level. Landings were applied to length samples combined by gearmonth, then combined to calendar quarters before applying quarterly age length keys. Canadian fishery weights were derived from fishery lengths using a length-weight relationship derived from commercial fishery samples (round weight $(\mathrm{kg})=0.0000158 \times$ length $(\mathrm{cm})^{2.91612}$; Waiwood and Neilson 1985).
The size composition of haddock discards in the 2014 Canadian scallop fishery was characterized by quarter using length samples obtained from 24 observed scallop trips which comprised $13 \%$ of the total trips (24 of 181) and 15\% of the total effort hours. Discards at age
for 2005-2012 were updated to reflect changes in estimated amounts due to a change in the effort measure used and changes made to the observer data (Sameoto et al. 2013). DFO survey ages ( $n=192$ ) for sets located in the Canadian portion of 5Zjm in 2014 were combined with port sample ages and applied to first quarter landings and discard length compositions. Fishery age samples for quarters 2, 3 and 4 were applied to the corresponding length compositions for both the groundfish fishery and discards.

Otter trawl contributed most to the 2014 catch at size ( $98 \%$ by number), followed by longline (1.5\%) and dredge discards (< 1\%) (Figure 7). Haddock captured by longline had the highest average size, followed by OTB and dredge (average fork length: Longline - 45 cm ; OTB - 43 cm ; Dredge -27 cm , with modes at 22 and 40 cm ). For both OTB and longline, over $80 \%$ of the catch was dominated by age 4 (2010 year class) while dredge catches consisted of $75 \%$ at age 1 (2013 year class) and 16\% at age 4 (2010 year class). Overall, the 2014 Canadian CAA was dominated by age 4 (2010 year class), then ages 3 (2011 year class) and 5 (2009 year class), representing $83 \%, 7 \%$ and $3 \%$ of total catch; the 2003 year class (age 11) represented less than 1\%. The 9+ age group, comprised almost exclusively of the 2003 year-class, represented $5 \%$ of quarter 1 Canadian landings, but only about 1\% in all remaining quarters (Table 10). The 2010 year class (age 4) was predominant in all four quarters, representing 78-86\% of catches.

## USA

USA landings of EGB haddock are sorted into "large", "scrod" and "snapper" market categories at sea and are sampled in port for lengths (FL) and ages (Table 11). In 2014, landings of large haddock totaled 58 mt , scrod haddock 765 mt and snapper 149 mt . Length sampling for USA EGB landings in 2014 was very limited, with no samples in quarter 1 for any market categories, and no samples of "snappers" in quarter 4. Length and age samples were pooled to estimate catch at age by half-year rather than by quarter, and were augmented with length and age samples from US statistical areas 522 and 525 . After augmenting samples, there was a total of 5,584 lengths and 2,532 ages for calculating the 2014 USA commercial fishery CAA. USA fishery weights were derived from fishery lengths using a length-weight relationship for each half year. For quarters 1 and 2, that equation is (round weight $(\mathrm{kg})=6.07 \mathrm{E}-06 \star$ length $(\mathrm{cm})^{3.10782}$; for quarters 3 and 4, that equation is (round weight $(\mathrm{kg})=7.12 \mathrm{E}-06^{*}$ length $(\mathrm{cm})^{3.08054}$.
USA fishermen are required to discard haddock under the legal size limit (18 inches/45.7 cm from January-June 2013, then 16 inches since July 2013). A new regulation for the 2010 fishing year required vessels participating in a sector to retain all legal sized haddock. USA discards at age of EGB haddock for calendar year 2014 were estimated by half-year from at-sea observer data. In calendar year 2014, the number of observed trips from the at-sea monitoring program was 95; a decrease from the previous year when there were 129. There were 561 trips to eastern Georges Bank for all groundfish gear types; however the fraction of trips sampled varied by gear: 34\% of standard otter trawl trips; 52\% of separator trawl trips; 13\% of scallop trips; 39\% for gillnet ( 2 out of 5 total trips); 4\% for lobster pot trips (7 out of 176 trips); and $0 \%$ for long line trips (0 out of 1 total long line trip).

As $97 \%$ of the discarding was due to the OTB fleet, there were few length samples from remaining gears (scallop dredge, gillnet, and lobster pot). Therefore, length samples were combined across gears. The resulting combined length frequencies by half-year were converted to discarded number at age by applying the age length keys from the NMFS spring bottom trawl survey ( 1073 ages) to quarters 1 and 2 and from the NMFS fall bottom trawl survey ( 768 ages) to quarters 3 and 4.
USA landings in 2014 had a modal size of 46 cm (Figure 8; upper panel). There were several modal sizes for discards depending on gear type. Haddock discards from OTB with a separator panel peaked at 20 cm , while without the panel they peaked at 20 and 28 cm . Scallop dredge discards had a modal size of 28 cm , while discards from lobster pots peaked at 28 and 44 cm .

The 2010 year class (age 4) represented 52\% of the CAA as landings while the 2013 year class (age 1) represented $37 \%$ of the CAA as discards (Figure 8; lower panel). Landings of the $9+$ age group (mostly the 2003 year class at age 11) represented less than $3 \%$ of the CAA (Table 11).

## Combined Canada/USA Catch at Age

The 2014 Canadian and USA landings and discards at age estimates (Table 1) were summed to obtain the combined annual catch at age and appended to the 1969 to 2013 CAA data (Table 12; Figure 9). The CAA tracks strong year classes well (i.e. 2000, 2003 and 2010) and showed an expansion in age structure in the mid-2000s with the contribution of the strong 2000 and 2003 year classes. The 2014 fishery was dominated by the 2010 year class (age 4), which represented $79 \%$ of the total catch by number ( $82 \%$ by weight), followed by the 2011 (age 3) and 2013 (age 1) year classes at 7\% and 6\%, respectively. Catches of older fish (6-9+) in 2014 were low and have declined in recent years. In comparison to the observed 2014 catch, the age composition of the catch projections made in 2013 and 2014 for the 2014 catch predicted similar percentages in number and weight for the 2010 year class, but were higher than observed for the 9+ group and lower than observed for age three (Figure 10).

There has been a declining trend in the combined Canada/USA commercial fishery weight at age (WAA) and length at age (LAA) since 2000 (Figure 11). Noteworthy is that the 2014 average fishery WAA (Table 13) and LAA (Table 14) are currently at or near the lowest values in the CAA time series (1969-2014). The average weight of age 4 haddock in 2000 was 1.9 kg with an average length of 55 cm . In 2014, the average weight and length of an age 4 haddock was 0.9 kg and 43 cm .

## ABUNDANCE INDICES

## RESEARCH SURVEYS

Surveys of Georges Bank have been conducted by DFO each year (February/March) since 1986 and by NMFS each fall (October/November) since 1963 and each spring (April) since 1968. All surveys use a stratified random design (Figures 12 and 13). The CCGS Alfred Needler is the standard vessel used for the DFO survey, but when unavailable, the CCGS Wilfred Templeman, a sister ship to the Needler, was used in 1993, 2004, 2007 and 2008. No conversion factors are available for the Templeman; however, this vessel is considered to be similar in fishing strength to the Needler. For the NMFS surveys, two vessels have been employed from 1963 to 2008 and there was a change in the trawl door type in 1985. Vessel and door type conversion factors, derived experimentally from comparative fishing, have been applied to the survey results to make the series consistent (Forrester et al. 1997). Additionally, two different trawl nets have been used on the NMFS spring survey, a modified Yankee 41 during 1973-81 and a Yankee 36 in other years, but no conversion factors are available for haddock so the indices are treated as separate series.

Since spring 2009, the NMFS surveys have been conducted with the NOAA FSV Henry B. Bigelow using a new net (4-seam, 3-bridle) and revised protocols. Length based conversion factors have been calculated and were applied by dividing Bigelow catches at length by the length specific conversion value to make the Bigelow survey catches equivalent to the FRV Albatross IV catches for both the NMFS spring and fall surveys (Brooks et al. 2010).

The spatial distributions of catches by age group (1, 2, and 3+ for spring and 0, 1 and 2+ for autumn) for the 2014 NMFS fall survey, and the 2015 DFO and NMFS spring surveys are shown in comparison to the average distribution over the previous 10-years (Figures 14-16). During the fall, age 0 is generally spread throughout the 5Zjm area but in 2014 many were
captured on the Canadian side along the northern and southern edges of the Bank. While age 1 haddock generally occur on the northern half of the Bank, they were mainly caught along the southern edge in 2014. The higher amount of age 1 (2013 year class) discards the USA fishery compared to the Canadian fishery may be attributed to spatial differences in areas fished by the Canadian and USA fleets as well as the distribution of the 2013 year class, which in 2014 was along the southern edge of the Bank in 5Zm below the area of the Canadian mobile gear fishery in 5Zj. Age 2+ fish were captured primarily in Canadian waters along the northern and southern edges, with a distribution similar to the 10 year average. In February-March (2015 DFO survey), age 1 and 2 haddock were distributed throughout the 5Zjm management unit somewhat more broadly than indicated by the 10-year average, while ages 3+ occurred mostly in Canadian waters along the northern part of the Bank similar to the 10-year average. In April-May (2015 NMFS spring survey), age 1-2 fish occurred throughout the stock area, generally similar to the
 Bank and were less widespread than the 10-year average.

Scaled total biomass indices (with various conversion factors applied to NMFS surveys for doors, vessels and nets) show that the three surveys are consistent and track each other well (Figure 17). Some year effects are evident but all three surveys show low biomass from the early-1980s to mid-1990s, followed by a steady increase to 2007, a decline to 2010-2011, followed by another strong increase from 2012-2015. The 2015 DFO survey index is the highest value for the time series (1986-2015), while the 2014 NMFS fall and 2015 NMFS spring values are at the second highest levels for their respective time series.

Age-specific total abundance indices for the three bottom trawl surveys track strong year classes (i.e. 2000, 2003 and 2010) quite well (Figure 18). The 2015 indices of abundance for the 2013 year class (age 2) from the DFO survey and NMFS spring surveys are at the highest levels observed for age 2 haddock over the time series (Tables 15 and 16). While the NMFS fall survey index for this year class (age 1) was considerably lower it was still relatively high for this time series (Table 17). The next highest index value was for the 2010 year class at age 4 in the 2014 NMFS fall survey and age 5 in the DFO and NMFS spring surveys.
Weights at age from the DFO survey are used as beginning of year population weights and are calculated using the method described in Gavaris and Van Eeckhaute (1998), in which weights observed from the survey are weighted by population numbers at length and age. Similar to the commercial fishery, the DFO survey WAA and LAA exhibit a declining trend from 2000 to present, especially for ages 3 and older (Tables 18 and 19; Figure 19).

## HARVEST STRATEGY

The Transboundary Management Guidance Committee (TMGC) has adopted a strategy to maintain a low to neutral risk of exceeding the fishing mortality limit reference, $F_{\text {ref }}=0.26$ (TMGC 2003). When stock conditions are poor, fishing mortality rates should be further reduced to promote rebuilding. The TMGC agreed to a common F strategy at its December 2002 TMGC meeting. The F references used by both countries for "healthy" or "rebuilt" stocks were virtually identical; that is, 0.25 for Canada and 0.26 for the USA (TMGC Meeting Summary, October 2, 2003).

## ESTIMATION OF STOCK PARAMETERS

## CALIBRATION OF VIRTUAL POPULATION ANALYSIS (VPA)

Calibrated Virtual Population Analysis (VPA) was used to estimate stock parameters. The adaptive framework, ADAPT, (Gavaris 1988) was used to calibrate the VPA with the research survey data. Details of the model formulations and model assumptions can be found in the 1998
benchmark assessment (Gavaris and Van Eeckhaute 1998). Data and model changes to the EGB haddock assessment framework from 1998 to 2015 are summarized in Appendix A.

The VPA was based on an annual CAA, Ca, $t$ for ages a $=0,1,2 \ldots 8,9+$, and time $t=1969$, 1970... 2014 where $t$ represents the beginning of the time interval during which the catch was taken. Catch discards were included in the CAA. The population was calculated to the beginning of 2015. The VPA was calibrated to bottom trawl survey abundance indices, Is, a, $t$ for:
$s=$ DFO, ages $a=1,2,3 \ldots 8$, time $t=1986.17,1987.17 \ldots 2014.17,2015.00$
$s=$ NMFS spring (Yankee 36), ages $a=1,2,3 \ldots 8$, time $t=1969.28 \ldots 1972.28$ and 1982.28...2014.28, 2015.00
$s=$ NMFS spring (Yankee 41), ages $a=1,2,3 \ldots 8$, time $t=1973.28,1974.28 \ldots 1981.28$
$s=$ NMFS fall, ages $a=0,1,2 \ldots 5$, time $t=1969.79,1970.79 \ldots 2014.79$.
Since the population is calculated to beginning year 2015, the DFO survey and NMFS spring survey in 2015 were designated as occurring at time 2015.00.

Statistical properties of estimators were determined using conditional non-parametric bootstrapping of model residuals (Efron and Tibshirani 1993, Gavaris and Van Eeckhaute 1998). Population abundance estimates at age 1 and 2 exhibit a large relative error of $60 \%$ and $39 \%$, respectively, and a large relative bias at age 1 of $14 \%$. The relative error for other ages was between $27 \%$ and $35 \%$ with a relative bias for ages 2 and older between $2 \%$ and $5 \%$ (Table 20). While trends in the three surveys are generally consistent, the survey indices exhibit high variability which is reflected in the magnitude and direction (i.e. positive or negative) of residual values (Figure 20). Some year and cohort effects are present throughout the time series. Noteworthy is that residuals were mostly negative for the 2015 NMFS spring and 2014 NMFS fall surveys (i.e. model predicts higher abundance than surveys). There was also a tendency for age 0 residuals from NMFS fall surveys to be positive for the past several years, but lower or negative for age 1 during the same period. This may contribute to the restospective pattern observed in this assessment over the past two years.

## Retrospective Analysis

A retrospective analyses was conducted for 2008-2015 to detect any trends to consistently overestimate or underestimate age 3-8 biomass, age 5-8 fishing mortality and age 1 recruitment relative to the terminal year estimates (Figure 21). Over the past two years, the addition of an extra year of data has caused a bias to appear between the present assessment results and previous assessments. Retrospective analysis shows lower biomass, higher F, and lower recruitment for several years of the analysis, while previous assessments remain consistent. A retrospective adjustment (denoted rho adjustment) based on the observed retrospective bias was applied to the terminal year estimates for comparisons of status determination following the methodology in Legault et al. (2010). Due to the recent increase in the retrospective pattern and the potential impact on assessment advice, a sensitivity projection was conducted using rhoadjusted age-specific stock abundance for 2015. Information on the relative change in age 3-8 biomass, age $5-8 \mathrm{~F}$ and age 1 recruits (Figure 22) was used to calculate a rho adjustment (Table 21), which was then applied to the terminal year estimates for comparisons of status determination. For the sensitivity projection, the age 3-8 biomass rho of 0.592 was used to adjust age specific stock abundance (for all ages) at the start of 2015, which in turn was used to calculate $3+$ biomass at the beginning of 2015. When the rho adjusted estimates for biomass and fishing mortality were plotted against the unadjusted values they were found to be well outside the $80 \%$ and $95 \%$ confidence intervals for the unadjusted estimates (Table 22,
Figure 23).

## STATE OF RESOURCE

Evaluation of the state of the resource was based on results from the VPA for the years 1969 to 2015. For each cohort, the terminal population abundance estimates from ADAPT were adjusted for bias estimated from the bootstrap and used to construct the history of stock status (Tables 23-24). This approach for bias adjustment was considered preferable to using potentially biased point estimates of stock parameters (O'Boyle 1998). The weights at age from the DFO survey (Table 18) were used to estimate beginning of year population biomass (Table 25). The adult (ages 3-8) population biomass trend generally reflects the $q$-adjusted survey biomass trends for the DFO survey and NMFS spring survey (ages 3-8), but was lower than indicated for the NMFS fall survey (ages 2-7) (Figure 24).

Adult biomass increased during the late-1970s and early-1980s to 38,000 mt in 1981 (Table 25; Figure 25). The increase was due to recruitment of the strong 1975 and 1978 year classes, which were both estimated to be above 50 million age- 1 fish. However, adult biomass declined rapidly in the early-1980s as these two cohorts were fished intensively at ages 2 and 3, and subsequent recruitment was poor. Improved recruitment in the 1990s and the strong 2000 year class ( 72 million at age 1), lower exploitation, and reduced capture of small fish in the fisheries allowed the biomass to increase from near a historical low of 10,300 mt in 1993 to $73,000 \mathrm{mt}$ in 2003. Adult biomass decreased to $50,000 \mathrm{mt}$ in 2005 , but subsequently increased to $102,000 \mathrm{mt}$ in 2009, higher than the 1931-1955 maximum adult biomass of about $90,000 \mathrm{mt}$. The near tripling of the biomass from 2005 to 2009 was due to the exceptional 2003 year-class, estimated at 210 million age-1 fish. The biomass decreased after the 2009 high and in 2012 the adult biomass was $30,000 \mathrm{mt}$ but increased in 2013, when the 2010 year class joined the $3+$ group, to $99,000 \mathrm{mt}$ and again in 2014 to $126,000 \mathrm{mt}$. The current estimate for 2015 is $117,000 \mathrm{mt}(80 \%$ confidence interval: 92,500-153,000 mt; Figure 26).
Except for the strong 2000 and 2011 year classes ( 72 and 34 million fish, respectively) and the exceptional 2003 ( 210 million) and 2010 ( 275 million) year classes, recruitment has fluctuated between 2.1 and 26.4 million age 1 fish since 1990. The current estimate of the 2013 year class at 1,300 million fish, which is the highest in the time series (1931-1955 and 1969-2014); the 2010 year class is the second highest in the series.
Since 2003, the age at full recruitment to the fishery has been 5 (rather than age 4 as in previous years) due to a decline in size at age (Table 14). Fully-recruited fishing mortality (population weighted average of fully recruited ages) is presented for ages 4-8 for pre-2003 and ages 5-8 for 2003 onwards (Table 24; Figure 27). Fully-recruited fishing mortality fluctuated between 0.28 and 0.50 during the 1980s. After reaching a high of 0.55 in 1993, it decreased to well below $F_{\text {ref }}$ in 1995, stayed below until 2003, fluctuated around 0.33 during 2004 to 2006, and then declined to 0.13 in 2008. Fishing mortality increased to levels above $F_{\text {ref }}$ from 20102012 before dropping off again in 2013. In 2014, F was estimates at 0.23 ( $80 \%$ confidence interval: 0.20-0.30; Figure 26), just below $\mathrm{F}_{\text {ref. }}$
Consistent with the increase in age at full recruitment into the fishery, the partial recruitment at age for EGB haddock is normalized to ages 4-8 population weighted F for 1969 to 2002 and to ages $5-8$ population weighted $F$ from 2003 onwards (Table 26; Figure 28). Average partial recruitment estimates are less variable when weighted by population numbers and are considered more appropriate than the unweighted average. The 10-year average partial recruitment (PR) values for 2005-2014 were used for projections of stock abundance in 2016 and 2017 (i.e. age 1: 0.003, age 2: 0.01, age 3: 0.11, age 4: 0.41, ages 5-8: 1.00 and age $9+$ : $0.26)$.

## PRODUCTIVITY

Recruitment, spatial distribution, age structure and growth generally reflect changes in productive potential. Recruitment, while highly variable, has generally been higher when adult biomass has been above 40,000 mt (Figure 29). Since 1969, only the 1975, 1978, 2000, 2003, 2010, 2011 and 2013 year classes have been above the average abundance of 40.5 million age 1 fish for year classes observed during the period 1931-1955 and 1969-2014. The very high age $3+$ biomass (generally greater than about 80,000 mt) observed since 2006 has produced two exceptional year classes, but has also produced four below average year classes (Figure 29).

The spatial distribution patterns observed during the most recent bottom trawl surveys were similar to the average patterns over the previous ten years for the spring surveys. Consistent with the pattern observed for previous exceptional year-classes, the 2013 year-class was widely distributed throughout the survey area, especially during the NMFS spring and fall surveys (Figures 14-16). Age structure as reflected in the commercial fishery and survey catch at age composition (i.e. Figures 9 and 18) indicate higher abundance of older fish (ages $5+$ ) since the mid-2000s.

An analysis of condition factor (Fulton's K; weight/length ${ }^{3}$ ) was conducted using available individual length and weight data from the DFO (1987-2015), NMFS spring (1992-2015) and NMFS fall (1992-2015) surveys for haddock $30-70 \mathrm{~cm}$ FL (i.e. where there was no change in condition at size) (Figure 30). The DFO survey data indicates that there has been a general decline in K over time with the 2015 value being the lowest in the series. Since 2004, Fulton's K has generally been at or below the long term average (1987-2015) for most years except 2009. The NMFS spring survey data also shows a decline in condition with $K$ falling below the series mean since 2000, but with an increasing trend since 2011. Fulton's K values from NMFS fall survey data are more variable but appear to have declined since 2003, with most values falling below the long term average since then with the exception of 2008, 2013 and 2014. Since this is a time of year when haddock would be feeding, it appears that in some years since 2003 they did not gain enough weight to bring the condition factor back to a level above average. Given the size of the exceptional 2003, 2010 and 2013 year classes there may also be densitydependent effects which could be limiting the growth of several cohorts since 2003. The overall pattern is consistent with declining trends in WAA and LAA for haddock, and is similar to trends in condition observed in Eastern Georges Bank cod (Wang and O'Brien 2013) and Georges Bank yellowtail flounder (Legault et al. 2013).
Both fishery and survey average lengths and weights at age have declined considerably since 2000 (Figures 11 and 19) with some values currently at or near the lowest levels for the commercial fishery (Tables 13-14) and DFO survey (Tables 18-19) time series. The DFO survey mean LAA for selected cohorts indicate that maximum size has decreased compared to the 1987 year class and that the recent strong 2013 year class has average lengths at ages 1 and 2 that are similar to the 2010 year class, values which are among the lowest in the time series (Figure 31). Changes in growth in response to changes in stock abundance and episodes of very strong recruitment have been observed throughout the history of this stock. Clark et al. (1982), reporting on Georges Bank haddock, observed "a decline in mean weight for all agegroups following every period of very strong recruitment" and a rapid increase in growth following the late-1960s and early-1970s reduction in stock size. As postulated by Clark et al. (1982), increased or decreased availability of food is probably the greatest determining factor for growth increases and decreases, respectively.
A comparison of total mortality $(Z)$ calculated for ages 3-8 from the DFO survey with VPA estimates of fishing mortality from the current assessment indicates that $Z$ has increased since the early- to mid-2000s for ages 3-6 and 8, while $F$ has generally decreased during this time (Figure 32). This is particularly evident for age 8 which exhibits a strong increase in $Z$ since

2001, with a concurrent decrease in F and may be indicative of an increase in natural mortality (M), as has been observed for older haddock in the adjacent 4X5Y stock (Stone and Hansen 2015).

In summary, positive signs of productivity include increased abundance for older ages, broad spatial distribution and large biomass. This stock has produced three exceptional and two strong year classes in the last 12 years. On the negative side, condition has decreased, growth has declined, recruitment from the very large biomass has been extremely variable and M may be increasing on older ages.

## OUTLOOK

This outlook is provided in terms of consequences with respect to the harvest reference point for alternative catch quotas in 2016 and 2017. Uncertainty about standing stock generates uncertainty in forecast results, which is expressed here as the risk of exceeding $F_{\text {ref }}=0.26$. The risk calculations assist in evaluating the consequences of alternative catch quotas by providing a general measure of the uncertainties. However, the risk calculations are dependent on the data and model assumptions and do not include uncertainty due to variations in WAA, PR to the fishery, M , systematic errors in data reporting or the possibility that the model may not reflect stock dynamics closely enough.

For projections, the most recent 3-year survey (2013-2015) and the lowest values for the fishery time series (1969-2014) average WAA were used for beginning year population (2016-2018) and fishery (2015-2017) WAA, respectively, except as indicated below. The 2015 DFO survey WAA were used for the 2015 population WAA, as this is consistent with the assessment results. The 2010 year class values were used for the 2013 year class at age 3 (2016), age 4 (2017) and age 5 (2018) due to similarity in growth. Fishery PR was based on the 2005 to 2014 population weighted average. The PR used for the age $9+$ group was 0.26 (Table 26). Ages 5 to 8 were considered fully-recruited to the fishery. EGB haddock are considered $100 \%$ mature at ages 3 and older.

## STANDARD PROJECTIONS

Incorporating the patterns in growth and PR (Table 27), deterministic projections and risk assessments were conducted to beginning year 2018 (Table 28). Stock size estimates at the beginning of 2015 were used to start the forecasts. Abundance of the 2016, 2017 and 2018 year classes were assumed to be 8.15 million fish at age 1 (the 2005 to 2014 median from the 2014 assessment results). Natural mortality was assumed to be 0.2. Assuming a 2015 catch equal to the $37,000 \mathrm{mt}$ total quota and $\mathrm{F}=0.26$ ( $\mathrm{F}_{\text {ref }}$ ) in 2016 and 2017, a combined Canada/USA catch of $37,500 \mathrm{mt}$ in 2016 results in a neutral risk (50\%) that the 2016 fishing mortality rate would exceed $F_{\text {ref }}=0.26$ (Figure 33). A catch of $32,000 \mathrm{mt}$ in 2016 results in a low risk (25\%) that the 2016 fishing mortality rate will exceed $F_{\text {ref. }}$. The 2010 year class at age 6 is expected to contribute $46 \%$ of the catch biomass and the 2013 year class at age 3 is expected to contribute the next highest percentage at $41 \%$. The probability that the 2017 biomass will not increase by $10 \%$ is negligible. Adult biomass is projected to be $522,000 \mathrm{mt}$, at the beginning of 2017 at the $\mathrm{F}_{\text {ref }}$ catch level.

A combined Canada/USA catch of 81,000 mt in 2017 results in a neutral risk (50\%) that the 2017 fishing mortality rate would exceed $F_{\text {ref }}=0.26$ (Figure 34). A catch of $66,000 \mathrm{mt}$ in 2017 results in a low risk (25\%) that the 2017 fishing mortality rate will exceed Fref. The 2010 year class at age 7 is expected to contribute $16 \%$ of the catch biomass and the 2013 year class at age 4 is expected to contribute $78 \%$. The probability that the 2018 biomass will not increase by $10 \%$ is high because population biomass is expected to decline from 2017 to 2018 (Table 28). Adult biomass is projected to be $464,000 \mathrm{mt}$ at the beginning of 2018 at the $\mathrm{F}_{\text {ref }}$ catch level.

## SENSITIVITY PROJECTIONS

A sensitivity forecast using the rho adjusted 2015 population numbers (ages 0-9+) for deterministic projections and risk assessments was conducted to beginning year 2018 (Table 29). All other input values for the forecast were the same as in Table 27. Assuming a 2015 catch equal to the $37,000 \mathrm{mt}$ total quota and $F=0.26$ ( $\mathrm{F}_{\text {ref }}$ ) in 2016 and 2017, a combined Canada/USA catch of $19,500 \mathrm{mt}$ in 2016 results in a neutral risk (50\%) that the 2016 fishing mortality rate would exceed $\mathrm{F}_{\text {ref }}$ (Figure 35). A catch of $16,000 \mathrm{mt}$ in 2016 results in a low risk (25\%) that the 2016 fishing mortality rate will exceed $F_{\text {ref. }}$. The 2010 year class at age 6 is expected to contribute $40 \%$ of the catch biomass and the 2013 year class at age 3 is expected to contribute $47 \%$. The probability that the 2017 biomass will not increase by $10 \%$ is negligible. Adult biomass is projected to be 299,000 mt at the beginning of 2017 at the $\mathrm{F}_{\text {ref }}$ catch level.

A combined Canada/USA catch of $45,000 \mathrm{mt}$ in 2017 results in a neutral risk (50\%) that the 2017 fishing mortality rate would exceed $\mathrm{F}_{\text {ref }}=0.26$ (Figure 36). A catch of $37,000 \mathrm{mt}$ in 2017 results in a low risk (25\%) that the 2017 fishing mortality rate will exceed $F_{\text {ref. }}$. The 2010 year class at age 7 is expected to contribute $13 \%$ of the catch biomass and the 2013 year class at age 4 is expected to contribute $82 \%$. The probability that the 2018 biomass will not increase by $10 \%$ is high because population biomass is expected to decline from 2017 to 2018 (Table 28). Adult biomass is projected to be 268,000 mt at the beginning of 2018 at the $\mathrm{F}_{\text {ref }}$ catch level.

The $F_{\text {ref }}$ catches from the sensitivity projections are considerably lower than the catches from standard projections, although they do take into account the emerging retrospective pattern which has occurred over the past two years in this assessment.

## MANAGEMENT ADVICE

There are reasons for considering both the standard projection and the sensitivity projection (rho adjusted) for catch advice. Reasons for using the standard projection include the survey biomass being at or near historic highs, recent recruitment (2010 and 2013) estimated to be the highest in the time series, expanded age structure, and success at projecting age composition of the fishery catch. Reasons for using the sensitivity projection include the overestimation of spawning stock biomass (SSB) and underestimation of $F$ in the last two assessments, the observation that terminal year biomass is lower than projected even though only about half of the quota was caught, and previous experience with assessments of other fish stocks of not accounting for retrospective bias leading to overfishing and further changes in perception of the stock status. For these reasons, both projections have been provided for consideration by the TMGC.

## SPECIAL CONSIDERATIONS

Catch projections for this stock can be highly influenced by outstanding year classes. There is no direct evidence to indicate that age 9 and older haddock should be less available to the fishery than age 8 haddock; however, the domed PR at age 9 and older that the assessment model produces may be aliasing increased M , emigration outside of the management area or to areas inaccessible to the fishery. The decision to use the lower PR produced by the model is also supported by the comparisons of percent predicted versus percent observed age 9+ from several recent assessments.

If the 2015 quota is caught, the projection indicates that the 2015 F will be above $\mathrm{F}_{\text {ref }}$ due to the revision of the size of the 2010 year class in the 2015 assessment.

In 2015, a large proportion of the exceptional 2013 year class will be below the current minimum size regulation used by the USA, which could lead to significant discarding. The reduction of the minimum size for the USA fishery in July 2013 from 18 inches to 16 inches will help to reduce
discarding of haddock. This is not expected to be an issue in the Canadian fishery due to the different gear types and management measures.

The terminal year rho adjusted SSB and rho adjusted F were well outside of both the $80 \%$ and $95 \%$ confidence intervals of the point estimates. This result indicates there is substantial unmeasured uncertainty, which has increased since last year's assessment.

Cod and haddock are often caught together in groundfish fisheries, although their catchabilities to the fisheries differ and they are not necessarily caught in proportion to their relative abundance. With current fishing practices and catch quotas, the achievement of rebuilding objectives for cod may constrain the harvesting of haddock. Modifications to fishing gear and practices, with enhanced monitoring, may mitigate these concerns.

The table in Appendix B summarizes the performance of the management system. It reports the TRAC advice, expected beginning of year 3+ biomass in the year following the catch year, the TMGC quota decision, actual catch, and realized stock conditions for this stock. Fishing mortality and trajectory of age 3+ biomass from the assessment following the catch year are compared to results from this assessment. These comparisons were kindly provided in 2011 by Tom Nies of the New England Fishery Management Council (NEFMC) and updated for this assessment. The largest differences in expected and actual results occurred when projection inputs for PR and WAA for large dominant year classes (i.e., 2000 and 2003) were higher than the realized values. When year class-specific input values were used the expected and actual results were similar. These results indicate that stock biomass is being adequately estimated by the model for management purposes, but, misspecification of PR and WAA, especially of very large and influential year classes, can result in higher than expected F due to catch advice being set too high.

## ACKNOWLEDGEMENTS

G. Donaldson and D. Frotten of DFO and at sea observers from Javitech Ltd. provided samples from the Canadian fishery. D. Knox and S. Sutherland provided ageing information for the DFO and NMFS surveys and Canadian and USA fisheries. K. Clark provided additional analyses and editing of the document. We also thank NMFS reviewers for their suggestions to improve the document.

${ }^{1} 1895 \mathrm{mt}$ excluded because of suspected area misreporting
${ }^{2}$ The USA quota pertains to the USA fishing year of May $1^{\text {st }}$ to April $30^{\text {th }}$ while the USA catches reported in this table pertain to the calendar year.
${ }^{3}$ USA landings and discards revised in 2011.

Table 2. Regulatory measures implemented for the $5 Z$ and EGB fishery management units by the USA and Canada, respectively, from 1977, when jurisdiction was extended to 200 miles for coastal states, to the present.

| Year | USA | Canada |
| :---: | :---: | :---: |
| 1977-82 | Mesh size of $51 / 8^{\prime \prime}(140 \mathrm{~mm})$, seasonal spawning closures, quotas and trip limits. |  |
| 1982-85 | All catch controls eliminated, retained closed area and mesh size regulations, implemented minimum landings size ( 43 cm ). | First 5Ze assessment in 1983. |
| Oct. 1984 | Implementation of the 'Hague' line, the boundary between Canada and the USA. |  |
| 1985 | $5^{1 / 2 "}$ mesh size, Areas 1 and 2 closed February-May. |  |
| 1989 |  | Combined cod-haddock-pollock quota for 4X5Zc |
| 1990 |  | EGB adopted as management unit. For mobile gear (MG) < 65 ft . - trip limits with a $30 \%$ by-catch of haddock to a maximum of 8 trips of 35,000 lbs per trip between June $1^{\text {st }}$ and October $31^{\text {st }}$ and minimum square mesh size 130 mm . <br> Fixed gear required to use large hooks until June |
| 1991 | Established overfishing definitions for haddock. | MG < 65 ft similar to 1990 but diamond mesh size increased to minimum 145 mm . |
| 1992 |  | Introduction of Individual Transferable Quotas (ITQ) and dockside monitoring. Total allowable catch $(T A C)=5000 \mathrm{mt}$. |
| 1993 | Area 2 closure in effect from January $1^{\text {st }}$ June $30^{\text {th }}$. | Otter trawl (OT) fishery permitted to operate in January and February. Increase in use of square mesh, minimum $130 \mathrm{~mm}) . \mathrm{TAC}=5000 \mathrm{mt}$. |
| 1994 | January: Expanded Area 2 closure to include June and increased extent of area. <br> Area 1 closure not in effect. <br> 500 lb trip limit. <br> Catch data obtained from mandatory log books combined with dealer reports (replaces interview system). <br> May: 6" mesh restriction. <br> December: Areas 1 and 2 closed year-round. | Spawning closure extended to January $1^{\text {st }}$ to May $31^{\text {st }}$. <br> Fixed gear vessels must choose between $5 Z$ or 4 X for the period of June to September. <br> Small fish protocol. <br> Increased at sea monitoring. <br> OT > 65 could not begin fishing until July $1^{\text {st }}$. <br> Predominantly square mesh, minimum <br> 130 mm by end of year. <br> TAC $=3000 \mathrm{mt}$. |
| 1995 |  | All OT vessels using square mesh, mimimum 130 mm . <br> Fixed gear vessels with a history since 1990 of 25 t or more for 3 years of cod, haddock, pollock, hake or cusk combined can participate in $5 Z$ fishery. <br> ITQ vessels require at least $2 t$ of cod and $8 t$ of haddock quota to fish Georges. TAC = 2500 mt . <br> Restrictions on catching of cod and haddock under 43 cm (small fish protocol). |
| 1996 | July: Additional Days-at-Sea restrictions, trip limit raised to 1000 lbs . | Fixed gear history requirement dropped. TAC $=4500 \mathrm{mt}$. |
| 1997 | May: Additional scheduled Days-at-sea restrictions. | All OT vessels using square mesh, mimimum 130 mm . |

| Year | USA | Canada |
| :---: | :---: | :---: |
|  | September: Trip limit raised to $1000 \mathrm{Ibs} /$ day, maximum of $10,000 \mathrm{lbs} /$ trip. | Vessels over 65 ft operated on enterprise allocations, otter trawlers under 65 ft on individual quotas, fixed gear vessels $45-65 \mathrm{ft}$ on self-administered individual quotas and fixed gear vessels under 45 ft on community quotas administered by local boards. TAC = $3,200 \mathrm{mt}$. |
| 1998 | Sept. 1: Trip limit raised to $3000 \mathrm{lbs} / \mathrm{day}$, maximum of $30,000 \mathrm{lbs} /$ trip. | All OT vessels using square mesh, mimimum 130 mm . <br> Fixed gear vessels $45-65 \mathrm{ft}$ operated on individual quotas. TAC $=3,900 \mathrm{mt}$. |
| 1999 | May 1: Trip limit 2,000 Ibs/day, max. 20,000 lbs/trip. <br> Square mesh size increased to $6.5^{\prime \prime}$ <br> (diamond is 6 "). <br> June 15 ${ }^{\text {th }}$ : Scallop exemption fishery in Closed Area II. <br> November $5^{\text {th }}$ : Trip limit 5,000 lbs/day, max. 50,000 lbs/trip. | All OT vessels using square mesh, mimimum 130 mm . <br> TAC $=3,900 \mathrm{mt}$.; mandatory cod separator panel when no observer on board. |
| 2000 | October: Daily trip limit suspended to April 2001but retained max. trip limit of 50,000 lbs/trip. | All OT vessels using square mesh, mimimum 130 mm . $\mathrm{TAC}=5,400 \mathrm{mt} .$ |
| $\begin{aligned} & \hline 2001- \\ & 2002 \end{aligned}$ | Day and trip limit adjustments. Daily trip limit suspended July 5, 2002. | All OT vessels using square mesh, mimimum 130 mm . <br> TAC $=6,989$ and 6,740 mt for 2001 and 2002 respectively. |
| $\begin{aligned} & \hline 2002- \\ & 2003 \end{aligned}$ | 30,000 - 50,000 lb/trip limit. <br> Trip limit suspended in October 2003. | All OT vessels using square mesh, mimimum 130 mm . <br> TAC $=6,933 \mathrm{mt}$ for 2003. |
| Canada - USA Resource Sharing Agreement on Georges Bank |  |  |
| 2004 | May $1^{\text {st }}$, day and trip limits removed. Quota management introduced. (Used primarily effort based management from 1994 to 2003.) TAC $^{1}=5,100 \mathrm{mt}$. October $1^{\text {st. }}$ : unit areas 561 and 562 closed to groundfish vessels. November 19 ${ }^{\text {th }}$ : Special Access Program (SAP) for haddock opened. Dec. 31: Haddock SAP closed. | All OT vessels using square mesh, mimimum 130 mm . $\mathrm{TAC}=9,900 \mathrm{mt} .$ |
| 2005 | TAC $^{1}=7,590 \mathrm{mt}$. January $14^{\text {th }}$ : separator trawl required. Fishery was closed in August when cod by-catch quota reached. | All OT vessels using square mesh, mimimum 130 mm . <br> TAC $=15,410 \mathrm{mt}$; exploratory winter fishery January to February 18, 2005. |
| 2006 | $\mathrm{TAC}^{1}=7,480 \mathrm{mt}$; EGB area closed to USA fishery in first half of year when USA cod quota nearly reached. | All OT vessels using square mesh, mimimum 130 mm . <br> TAC $=14,520 \mathrm{mt}$; exploratory winter fishery January to February 6, 2006. |
| 2007 | TAC $^{1}=6,270 \mathrm{mt}$. June 20: EGB area closed to USA fishery due to USA cod catch nearing quota. August $9^{\text {th }}$ : Minimum haddock size reduced to 18 inches; October 20: EGB area opened to USA fishery. | All OT vessels using square mesh, mimimum 130 mm . <br> TAC $=12,730 \mathrm{mt}$; exploratory winter fishery January to February 15, 2007 |

| Year | USA | Canada |
| :---: | :---: | :---: |
| 2008 | TAC $^{1}=8,050 \mathrm{mt}$. Minimum size reverts back to 19 in. in August. Prohibitions on yellowtail flounder fishing January $24^{\text {th }}$ to April $30^{\text {th }}$. Trawl fishery opening delayed until August $1^{\text {st }}$. Ruhle trawl (type of separator trawl) approved for use beginning September $15^{\text {th }}$. Restrictions on cod catches. | All OT vessels using square mesh, mimimum 130 mm . <br> TAC $=14,950 \mathrm{mt}$; winter fishery January 1 to February 8, 2008. |
| 2009 | TAC $^{1}=11,100 \mathrm{mt}$. <br> May $1^{\text {st: }}$ Interim action by NMFS set the minimum size at 18 inches. <br> Trawl fishery opening delayed until August $1^{\text {st }}$. | All OT vessels using square mesh, mimimum 130 mm . <br> TAC $=18,900 \mathrm{mt}$; winter fishery January 1 to February 7, 2009. Industry test fishery/survey in deep water in February to assess spawning condition of haddock in deep water. Test fishery terminated after 2 trips. |
| 2010 | TAC $^{1}=11,988 \mathrm{mt}$ <br> May 1, 2010: Sector Management with Annual Catch Entitlements (ACEs) and accountability measures implemented (Amendment 16). Minimum haddock size limit of 18 inches retained in Amendment 16, effective May $1^{\text {st }}$. All legal size fish must be retained by sector vessels. Trawl fishery opening delayed until August $1^{\text {st }}$. | All OT vessels using square mesh, mimimum 130 mm . <br> TAC $=17,612 \mathrm{mt}$; winter fishery January 1 to February 7, 2010. |
| 2011 | $\mathrm{TAC}^{1}=9,460 \mathrm{mt}$ Common pool fishery (very small percentage of quota) closed May $1^{\text {st }}$ to July $31^{\text {st }}$. On May $11^{\text {th }}$ the Closed Area II Special Access Permit (SAP) modified to allow targeting of haddock from August $1^{\text {st }}$ to January $31^{\text {st }}$. <br> On September $14^{\text {th }}$ haddock catch cap regulation for herring midwater trawl fishery increased to $1 \%$ of the Georges Bank Annual Biological Catch (ABC). | All OT vessels using square mesh, mimimum 130 mm . <br> TAC $=12,540 \mathrm{mt}$; winter fishery January 1 to February 6, 2011. |
| 2012 | $\mathrm{TAC}^{1}=6,880 \mathrm{mt}$ Common pool fishery (very small percentage of quota) closed May $1^{\text {st }}$ to July $31^{\text {st }}$. | All OT vessels using square mesh, minimum 130 mm . <br> TAC $=9,120 \mathrm{mt}$; winter fishery January 1 to February 4, 2012. |
| 2013 | $\mathrm{TAC}^{1}=3,952 \mathrm{mt}$ July: Minimum size reduced from 18 " to $16^{\prime \prime}$ Common pool fishery (very small percentage of quota) closed May $1^{\text {st }}$ to July $31^{\text {st }}$. | TAC $=6,448 \mathrm{mt}$; winter fishery January 1 to February 4, 2013. <br> All OT vessels using square mesh, minimum 130 mm . |
| 2014 | $\mathrm{TAC}^{1}=10,530 \mathrm{mt}$ Common pool fishery (very small percentage of quota) closed May $1^{\text {st }}$ to July $31^{\text {st }}$. | TAC $=16,470 \mathrm{mt}$; winter fishery January1 to February 3, 2014. <br> Experimental use of 145 mm diamond mesh in winter fishery. Starting in June, 145 mm diamond use continued and experimental use of 125 mm square. Continued use of 130 mm square. |

Table 13. Average weight at age (kg) of haddock from the combined Canadian and USA commercial groundfish fishery landings on eastern Georges Bank during 1969-2014. For 1969-1973 only USA fishery sampling for lengths and ages was available; for 1974-1984 a mix of USA and Canadian samples were used. For missing age 1 weights (bold), an average of 0.600 kg was used. Missing weights for older haddock were extrapolated within year class. Values for the exceptionally strong 2003 and 2010 year class values are highlighted in yellow.

| Year | Age Group |  |  |  |  |  |  |  |  |

Table 16. Total swept area estimated abundance at age (numbers in 000's) of EGB haddock from the NMFS spring surveys during 1968-2015. From 1973-1981, a 41 Yankee trawl was used while a 36 Yankee trawl was used in other years up to and including 2008. Since 2009 a new net, vessel and protocols were used and conversion factors to equate to Albatross IV catches were applied.

Table 17. Total swept area estimated abundance at age (numbers in 000's) of EGB haddock from NFMS fall surveys during 1963-2014. Since 2009 a new net, vessel and protocols were used and conversion factors to equate to Albatross IV catches were applied.

| Year | Age Group |  |  |  |  |  |  |  |  |  |

| 6 | 3.05 | 0.66 | -0.360 |
| 7 | 1.97 | 0.70 | -0.261 |
| Rho | 1.07 | 0.69 | -0.41 |
| \% | 0.483 | 0.592 | 1.695 |
| Adjustment ${ }^{1}$ |  |  |  |

Table 22. Estimated and rho adjusted values for fishing mortality for ages 5 to $8\left(F_{5-8}\right)$ and 3+ biomass $\left(B_{3+}\right)$, and confidence intervals (CI) for the original estimated values of $F_{5-8}$ and $B_{3+.}$. Note the $\%$ rho adjustment value of 0.592 for Age 3-8 biomass was used to adjust the age 3+ biomass estimate at the beginning of 2015.

| Parameter | Original Estimate | Rho Adjusted Estimate | 80\% CI | 95\% CI |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{B}_{3+}(\mathrm{mt})$ | 116,970 | 69,012 | 92,500 to 153,000 | 77,263 to 174,408 |
| $\mathrm{F}_{5-8}$ | 0.23 | 0.39 | 0.20 to 0.30 | 0.18 to 0.34 |

Table 23. Beginning of year population abundance (numbers in 000's) for EGB haddock during 19692015 from a virtual population analysis (VPA) using the bootstrap bias adjusted population abundance at the beginning of 2015. Highlighted cells follow recent large year classes, 2000, 2003, 2010 and 2013.

| Year | Age Group |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 24. Fishing mortality rates for EGB haddock during 1969-2014 from a VPA using the bootstrap bias adjusted population abundance at the beginning of 2015. The aggregated rates are weighted by population numbers. The rates for ages 4 to 8 and 5 to 8 are also shown as exploitation rate (\%).
Highlighted cells follow recent large year classes: 2000, 2003 and 2010.

Table 25. Beginning of year biomass (mt) for EGB haddock during 1969-2015. Weights at age from the DFO survey were applied to the VPA bootstrap bias adjusted population numbers at age at the beginning of 2014 to determine biomass. Highlighted cells follow recent large year classes: 2000, 2003, 2010 and 2013.

Table 26. Partial recruitment of haddock normalized to ages 4 to 8 for 1969 to 2002 and to ages 5 to 8 for 2003 to 2014 from the eastern Georges Bank fishery. Average F's used to normalize the partial recruitment were weighted by population numbers. Highlighted cells follow recent large year classes: 2000, 2003, 2010 and 2013.

${ }^{1}$ Based on 2005 to 2014 weighted average; used for 20152016 and 2017.
${ }^{2}$ 2012-2014 average weights at age from the DFO survey unless indicated otherwise.
${ }^{3} 2015$ average weights at age from DFO survey.
${ }^{4} 2010$ year class average weights at age from DFO survey used for 2013 year class.
${ }^{5}$ Lowest values in the time series (1969-2014); used for 2015, 2016 and 2017.

Table 28. Bias adjusted deterministic projection results for EGB haddock for the 2016 and 2017 fishery using 8.2 million age 1 recruits (2005 to 2014 median from 2014 assessment results) for the 2015, 2016 and 2017 year classes, the input values detailed in Table 25 and assuming that the 2015 quota of $37,000 \mathrm{mt}$ is caught and $F=0.26$ in 2016 and 2017. Natural mortality was assumed to be 0.2. Highlighted values indicate the 2013 and 2010 year classes.

Table 29. Bias adjusted sensitivity projection results for EGB haddock for the 2016 and 2017 fishery with a rho adjustment (=0.592) applied to the 2015 population numbers for ages 0-9+. The projections use 8.2 million age 1 recruits (2005 to 2014 median from 2014 assessment results) for the 2015, 2016 and 2017 year classes (see Table 25). It is assumed that the 2015 quota of 37,000 mt is caught and that $F=0.26$ in 2016 and 2017 ; natural mortality $=0.2$. Highlighted values indicate the 2013 and 2010 year classes.

FIGURES

Figure 1. Fisheries statistical unit areas in North Atlantic Fisheries Organization Subdivision 5Ze. Alpha-numeric codes, e.g. 5Zej, are the Fisheries and Oceans Canada (DFO) designations and numeric codes, e.g. 561, are U.S. National Marine Fisheries Service (NMFS) designations. The eastern Georges Bank management unit is outlined by a heavy red line.

Figure 2. Historical catch of EGB haddock during 1931-1955 (Gavaris and Van Eeckhaute 1998) compared to recent catches during 1969-2014. Catch data for 1956 to 1968 were not available by unit area.

Figure 3. Nominal catches of EGB haddock during 1969-2014.

Figure 4. Percentage of annual landings by gear type for the EGB haddock fishery, 1969-2014. TC 1-3 = OTB tonnage class 1-3; TC 4+ = OTB tonnage class 4+; LL = longline; Side = side otter trawl.

Figure 5. Haddock landings by the Canadian commercial groundfish fishery and discards from the scallop fishery from eastern Georges Bank by month and gear in 2014 (wide bars) with sampling levels (narrow bars). Landings from the gillnet fishery were very low and no samples were available. OTB = otter trawl bottom, $L L=$ longline, $G N=$ gill net, and $D R=$ scallop dredge.

Figure 6. Size composition of EGB haddock by quarter sampled by at-sea observers from otter trawls with different cod end mesh size and type used in the 2014 Canadian fishery: 145 mm diamond mesh ( 145 dia ); 130 mm square mesh ( 130 sq ); and 125 mm square mesh ( 125 sq ).

Figure 7. Canadian EGB haddock fishery catch at size (left panels) and catch at age (right panels) in numbers and percentage by gear category for 2014. OTB = otter trawl bottom, $L L=$ longline, and $D R=$ scallop dredge.

Figure 8. USA EGB haddock fishery catch at size (top panel) and catch at age (bottom panel) in percentage for landings and discards in 2014.

Figure 9. Total commercial catch at age (numbers) of EGB haddock during 1969-2014. The 2000, 2003 and 2010 year classes are indicated in blue, purple and dark blue, respectiviely. The bubble area is proportional to catch magnitude.

Figure 10. Percent compostion in numbers and biomass of 2014 observed EGB haddock landings predicted in 2013, upon which the quota was based, and in 2014.

Figure 11. Average weights at age (upper panel) and lengths at age (lower panel) for EGB haddock from the combined Canadian and USA commercial groundfish fishery for 1969-2014.

Figure 12. Stratification scheme used for NMFS surveys. The eastern Georges Bank management area is indicated by shading.

Figure 13. Stratification scheme used for the DFO survey. The eastern Georges Bank management area is indicated by shading.

Figure 14. Distribution of EGB haddock abundance (number/tow) as observed from the NMFS fall survey for ages 0,1 and 2+. The squares (left panels) are shaded relative to the average survey catch for 2004 to 2013. The expanding symbols (right panels) represent the 2014 survey catches. Length based conversion coefficients have been applied since the 2009 survey to make them comparable to surveys undertaken by the Albatross IV.

Figure 15. Distribution of EGB haddock abundance (number/tow) as observed from the DFO survey for ages 1, 2 and 3+. The squares (left panels) are shaded relative to the average survey catch for 2004 to 2013. The expanding symbols (right panels) represent the 2015 survey catches.

Figure 16. Distribution of EGB haddock abundance (number/tow) as observed from the NMFS spring survey. The squares (left panels) are shaded relative to the average survey catch for 2005 to 2014. The expanding symbols (right panels) represent the 2015 survey catches. Length based conversion coefficients have been applied since the 2009 survey to make them comparable to surveys undertaken by the Albatross IV.

Figure 17. Scaled total biomass indices from NMFS fall (1963-2014), NMFS spring (1968-2015) and DFO (1987-2015) research surveys for eastern Georges Bank. Biomass conversion coefficients have been applied to the NMFS surveys to adjust for changes in door type (BMV vs Polyvalent; 1968-1984), vessel (Delaware II vs Albatross IV; 1968-2008) and vessel/net (Albatross IV vs Henry B. Bigelow; Yankee 36 vs 4 seam-3 bridle; 2009-2015).

Figure 18. Estimated abundance at age (numbers in O00's) of EGB haddock from the DFO survey for 1986 to 2014, NMFS spring survey for 1968 to 2014, and NMFS fall survey for 1963 to 2013. Bubble area is proportional to magnitude (see: Tables 18-20). Conversion factors to adjust for changes in door type and survey vessel were applied to the NMFS surveys. From 1973-81 (yellow circles), a 41 Yankee trawl was used for the NMFS spring survey while a 36 Yankee was used in the other years. Length based conversion coefficients have been applied to the NMFS surveys since the 2009 survey to make them comparable to surveys undertaken by the Albatross IV. Symbol size has not been adjusted between surveys for the catchability of the survey.

Figure 19. Average weights (upper panel) and lengths (lower panel) at age for EGB haddock derived from DFO surveys during 1986-2015.

Figure 20. Residuals of survey abundance indices by year and age group from the DFO survey (1986-2015), NMFS spring survey (1969-2015) and NMFS fall survey (1969-2014) for EGB haddock. Solid symbols indicate positive values (i.e. model predicts lower abundance than surveys), open symbols indicate negative values (i.e. model predicts higher abundance than surveys). Bubble area is proportional to magnitude. From 1973-81 (light blue circles), a Yankee 41 trawl was used for the NMFS spring survey while a Yankee 36 trawl was used in the other years.

Figure 21. Retrospective results from virtual population analysis (VPA) for EGB haddock for biomass (ages 3-8), fishing mortality (ages 5-8), and recruitment (age 1), as successive years of data are removed from the assessment. The most recent assessment results are indicated in red.

Figure 22. Relative retrospective results from VPA for EGB haddock for biomass (ages 3-8), fishing mortality, (ages 5-8) and recruitment (age 1), as successive years of data are removed from the assessment. Changes are relative to the 2015 assessment.

Figure 23. Estimate of fishing mortality on ages 5 to 8 and ages 3+ biomass estimated using the Benchmark VPA formulation (blue square) and the rho adjusted value (orange circle). The solid lines show the $80 \%$ confidence interval around the benchmark estimate, while the dotted lines show the 95\% confidence interval. Note the $\%$ rho adjustment value of 0.592 for Age 3-8 biomass was used to adjust the age 3+ biomass estimate at the beginning of 2015.

Figure 24. The 1969 to 2015 eastern Georges Bank adult haddock (ages 3-8) biomass from VPA compared with the survey adult biomass (scaled with catchabilities) for ages 3-8 (DFO and NMFS spring) and ages 2-7 (NMFS fall).

Figure 25. Beginning of year adult (3+) biomass and number of age 1 recruits for $E G B$ haddock during 1931-1955 and 1969-2015.

Figure 26. Cumulative probability distribution with $80 \%$ confidence intervals for 2015 age 3+ biomass (000 mt) and 2014 age 5-8 fishing mortality for EGB haddock. Cl for biomass $=92,000-153,000 \mathrm{mt}$; CI for $F=0.20-0.30$.

Figure 27. Fishing mortality rate (weighted by population) for EGB haddock ages 4+ and 5+ during 19692014 and the fishing mortality threshold reference established at $F_{\text {ref }}=0.26$.

Figure 28. Partial recruitment of EGB haddock for the population weighted average of 1998-2002, 20052014, 2012-2014 and for the 2003 year class. The partial recruitment is normalized to ages 4-8 for years before 2003 and to ages 5-8 for years after 2002.

Figure 29. Relationship between eastern Georges Bank adult (ages 3+) haddock biomass during 19311955 and 1969-2014 and recruits at age 1. The year classes since the 2000 are labeled in red font.

Figure 30. Annual mean condition as indicated by Fulton's $K\left(W / L^{3}\right)$ for EGB haddock (30-70 cm FL) from the DFO survey (1986-2015; top panel), NMFS spring survey (1992-2015; middle panel) and NMFS fall survey (1992-2014; lower panel). Red dashed line is mean value for survey time series.

Figure 31. Mean length at age for selected year classes of EGB haddock sampled from the DFO survey.

Figure 32. EGB haddock total mortality (Z; 3-year smooth) for ages 1-8 from DFO survey catch at age data, 1986-2014 compared to F for age 1-8 (F; 3-year smooth) calculated from the 2015 VPA model output.

Figure 33. Risk of 2016 fishing mortality exceeding $F_{\text {ref }}=0.26$ for $E G B$ for increasing catch quotas.

Figure 34. Risk of 2017 fishing mortality exceeding $F_{\text {ref }}=0.26$ for EGB haddock for increasing catch quotas.

Figure 35. Sensitivity risk analysis of 2016 fishing mortality exceeding $F_{\text {ref }}=0.26$ for EGB haddock for increasing catch quotas. A rho adjustment (0.592) was applied to down weight the 2015 population estimates prior to conducting risk calculations.

Figure 36. Sensitivity risk analysis of 2017 fishing mortality exceeding $F_{\text {ref }}=0.26$ for EGB haddock for increasing catch quotas. A rho adjustment (0.592) was applied to down weight the 2015 population estimates prior to conducting risk calculations.

## APPENDICES

Appendix A. Data and model changes to the EGB haddock assessment framework from 1998 to 2015.

| Assessment Year | Change |
| :---: | :---: |
| 1998 | Framework: <br> Random error in catch at age negligible. <br> Error in abundance indices assumed independent and identically distributed after taking the natural logarithms. <br> Annual natural mortality rate $(M)=0.2$. <br> Fishing mortality $(F)$ on age $8=$ weighted $F$ on ages 4 to 7 . <br> $9+$ age group calculated but not calibrated to indices. <br> In Q1 of first year, 9+ based on assumption that F9+ = popn weighted F4-8. In Q1 of subsequent years, 9+ abundance calculated as sum of age 8 and $9+$ at end of last quarter of previous year. <br> Quarterly catch at age: $0,1,2 \ldots 8,9+; 1969.0,1969.25,1969.75,1970.0 \ldots 1996.75$. <br> DFO survey: ages $1,2,3 \ldots 8 ; 1986.16,1987.16 \ldots 1998.0$. <br> NMFS spring (Yankee 36): age 1,2,3...8; 1969.29, 1970.29...1997.29. <br> NMFS spring (Yankee 41): age 1,2,3...8; 1973.29, 1974.29...1981.29. <br> NMFS fall: 0,1,2..5, 1969.69, 1970.69...1997.69. <br> Zero survey observations treated as missing data. |
| 1999 | Minor differences in the handling of zero terminal catches for a year class were implemented as a refinement to the software to afford more flexibility. |
| 2003 | NMFS spring (Yankee 36): age 1,2,3...8; 1969.29, 1970.29...2003.25. (In previous years, the last survey available was the same year as the last catch at age year.) Catch of 0 was assumed for the $1^{\text {st }}$ quarter of 2003 and the population calculated to beginning of 2003.25. |
| 2005 | Discards ages 1 and older from Canadian scallop fishery included in catch at age but age 0 set to zero. <br> Population calculated to beginning year 2005. <br> NMFS and DFO spring surveys in 2005 set to time=2005.00. |
| 2007 | Discards at age 0 included in catch at age. |
| 2008 | 1) an annual catch at age instead of a quarterly catch at age. <br> 2) revised survey timing: DFO spring from 0.16 to 0.17 , NMFS spring from 0.29 to 0.28 and the NMFS fall survey from 0.69 to 0.79 . <br> 3) a change from ages 4 to 7 to 5 to 7 (weighted by population numbers) used to estimate oldest age F from 2003 to present. |
| 2009 | USA 2007 catch corrected from previous year (calculation error). <br> The landings at age for 2006 to 2007 were recalculated. <br> USA landings for 1994 to 2007 revised using new methodology. (Effect was negligible.) <br> USA landings at age from 1991 to 2005 were revised to reflect the recalculated landings using a scalar adjustment. <br> USA discards recalculated using ratio of discarded haddock to kept of all species for 1989 to 2007. <br> Discards at age were not revised for 1989 to 2000 as amounts were low, except for 1994 (old $=258$ vs new $=1,021 \mathrm{mt}$ ). No adjustment to the 1994 discards at age was made due to the uncertainty of this estimate. <br> Discard at age estimates for 2001 to 2007 were revised by a scalar. <br> 2009 NMFS spring survey not used (no conversion factors). |
| 2010 | 9+ group in catch at age expanded to 9 to 16+; ages 15 and 16 dropped; 9+ group reconstructed from ages 9 to 14 . <br> Revisions made to USA landings, Canadian scallop discards and USA groundfish fishery discards at age. Largest change for 1994 discards from 258 mt to 1279 mt . |
| 2011-2013 | No additional changes. <br> Note that the 2010 fall survey was used at twice its actual value in the 2011 and 2012 assessments. The effect on the 2012 assessment results are as follows: |

| Assessment Year | Change |
| :---: | :---: |
|  | - 2010 yc declined from 589 M to 532 M <br> - 1+ population declined from $644,586 \mathrm{~K}$ to $597,434 \mathrm{~K}$ <br> - 3+ population declined from 57,745 to $55,964 \mathrm{~K}$ <br> - 3+ biomass declined from $70,679 \mathrm{mt}$ to $68,521 \mathrm{mt}$ <br> - risk analysis for $2013 F_{\text {ref }}$ catch declined by 700 mt from $10,400 \mathrm{mt}$ to $9,700 \mathrm{mt}$ |
| 2014 | NMFS 2012 spring survey: <br> For the 2012 and 2013 assessments the survey results did not incorporate some lengths for which there were no ages. The numbers involved were small. Updated values also reflect an increase in the number of tows, changes to the numbers per tow and a large increase in the numbers aged. <br> NMFS 2011 fall survey: <br> The NMFS 2011 fall survey used incorrect stratum area values for strata $5 Z 3$ and $5 Z 4$ for the 2012 and 2013 assessments. Updated values also reflect changes to the numbers per tow. <br> Canadian scallop discards: <br> Revised 2005 to 2012 to reflect updated values due to change from freezer trawler equivalents to hours $x$ meters as new effort measure and other data changes. Largest percent difference from previous values for age/year was 19\%. Largest annual change was $7 \%$. Canadian scallop discards contribute a very small amount to the total catch. |
| 2015 | Retrospective pattern which emerged in 2014 persisted in 2015 |

Appendix B. Comparison of EGB haddock Transboundary Resource Assessment Committee (TRAC) catch advice, Transboundary Management Guidance Committee (TMGC) quota decision, actual catch, resulting fishing mortality and biomass changes. All catches are calendar year catches. In the "Results" column, values in italics are assessment results in the year immediately following the catch year; values in normal font are results from the 2015 assessment.
