#### Abstract

The combined 2014 Canada/USA Atlantic Cod catches were 574 mt with a quota of 700 mt . Catches in the National Marine Fisheries Service (NMFS) fall and spring surveys decreased from 2014, and catches from all three research surveys were among the lowest in the time series. Both fishery and survey catches showed truncated age structure in recent years.

The Virtual Population Analysis (VPA) "M 0.8" model from the 2013 benchmark assessment was used to provide catch advice in conjunction with a consequence analysis of the uncertainties in the VPA "M 0.8 " and ASAP model results. In the VPA "M 0.8 " model, natural mortality (M) was assumed to be 0.2 except $\mathrm{M}=0.8$ for ages $6+$ since 1994 , whereas in the ASAP model $M=0.2$ for all ages and years.

While management measures have resulted in a decreased exploitation rate since 1995, total mortality has remained high and adult biomass has fluctuated at a low level. The adult population biomass at the beginning of 2015 was estimated at $10,048 \mathrm{mt}$, which was about $20 \%$ of the adult biomass in 1978. Fishing mortality was high prior to 1994 and was estimated to be 0.04 in 2014, the lowest on record. Recruitment at age 1 has been low in recent years. High natural mortality, lower weights at age in the population in recent years and poor recruitment have contributed to the lack of rebuilding.

In 2016, a $50 \%$ probability of not exceeding fishing reference point $F=0.11$ corresponds to catches of 675 mt . However, given the extremely low spawning stock biomass (SSB), the Transboundary Resources Assessment Committee (TRAC) advises that management aim to rebuild Spawning Stock Biomass (SSB). Even with no fishing in 2016 there is a greater than $50 \%$ risk of a decrease in adult biomass from 2016 to 2017, and a catch of 475 mt would result in at least a $75 \%$ risk that 2017 adult biomass would decrease.

In 2017, a $50 \%$ probability of not exceeding $\mathrm{F}=0.11$ corresponds to a catch of 725 mt . A catch of 625 mt will result in a neutral ( $50 \%$ ) risk that 2018 age $3+$ biomass will be lower than 2017, whereas a catch of 225 mt has a lower ( $25 \%$ ) risk.

Discovery that the risk analysis did not account for the differences in natural mortality rate between young ages and ages 6+ could have impacted catch advice since 2009. Considering the current status of the stock, the TRAC recommends that the risk calculations provided remain appropriate despite the unaccounted for age specific difference in the stochastic projections.

A consequence analysis to understand the risks associated with assumptions of the VPA " M 0.8 " and ASAP "M 0.2 " model was examined in the projection and risk analysis. The consequence analysis reflects the uncertainties in the assessment model assumptions. Despite model uncertainties, all assessment results indicate that low catches are needed to promote rebuilding.

## RÉSUMÉ

En 2014, les prises de morues franches combinées du Canada et des États-Unis se sont chiffrées à 574 tm , sur un quota de 700 tm . Les prises des relevés d'automne et de printemps effectués par le National Marine Fisheries Service (NMFS) ont diminué par rapport à 2014, et les prises des trois relevés de recherche comptaient parmi les plus basses de la série chronologique. Au cours des dernières années, les prises de la pêche et des relevés ont montré une structure selon l'âge tronquée.

Le modèle d'analyse de population virtuelle (APV) «M = 0,8 » de l'évaluation de référence de 2013 a été utilisé pour faire des recommandations en matière de prises en plus d'une analyse des conséquences des incertitudes liées aux résultats du modèle d'APV «M=0,8 » et du modèle du PESA. Dans le modèle d'APV « $M=0,8 »$, la mortalité naturelle ( $M$ ) est estimée à 0,2 , sauf pour les individus de 6 ans et plus, où $M=0,8$ depuis 1994, tandis que dans le modèle du Programme d'évaluation selon la structure d'âge (PESA), la mortalité naturelle est estimée à 0,2 pour tous les âges et toutes les années.

Quoique les mesures de gestion aient eu pour effet de faire baisser le taux d'exploitation depuis 1995, la mortalité totale est demeurée élevée et la biomasse des adultes a fluctué tout en restant faible. La biomasse de la population adulte était estimée à 10048 tm au début de 2015, ce qui correspondait à environ $20 \%$ de la biomasse des adultes de 1978. La mortalité par pêche était élevée avant 1994 et elle a été estimée à 0,04 en 2014, soit le niveau le plus faible jamais enregistré. Le recrutement à l'âge 1 a été faible ces dernières années. Au cours des dernières années, la mortalité naturelle élevée, les plus faibles poids selon l'âge au sein de la population et le faible recrutement ont nui au rétablissement du stock.
En 2016, une probabilité de 50 \% que le taux de mortalité par pêche ne dépasse pas le point de référence de la pêche où $F=0,11$ suppose des prises de 675 tm . Toutefois, le Comité d'évaluation des ressources transfrontalières (CERT) recommande que les gestionnaires tentent de rétablir la biomasse du stock reproducteur (BSR) qui est extrêmement faible. Même sans pêche en 2016 suppose qu'il existe un risque de plus de $50 \%$ d'une diminution de la biomasse des adultes de 2016 à 2017, et des prises de 475 tm se traduiraient au minimum par un risque de 75 \% d'une diminution de la biomasse des adultes de 2017.
En 2017, une probabilité de $50 \%$ que le taux de mortalité par pêche ne dépasse pas $F=0,11$ suppose des prises de 725 tm . Des prises de 625 tm se traduiraient par une probabilité neutre ( $50 \%$ ) que la biomasse des adultes de 3 ans et plus de 2018 soit inférieure à 2017, tandis que des prises de 225 tm présenteraient un risque inférieur ( $25 \%$ ).
La découverte que l'analyse des risques ne tenait pas compte des différences des taux de mortalité naturelle entre les jeunes poissons et les âges de 6 ans et plus pourraient avoir eu une incidence sur les recommandations en matière de prises depuis 2009. En tenant compte de l'état actuel des stocks, le CERT croit que le calcul des risques fourni demeure approprié, malgré la différence spécifique à l'âge qui n'est pas prise en compte dans les projections stochastiques.
Dans la projection et l'analyse des risques, on a examiné les résultats d'une analyse des conséquences, afin de comprendre les risques associés aux hypothèses du modèle d'APV « $M=0,8$ » et du modèle du PESA « $M=0,2$ ». L'analyse des conséquences reflète les incertitudes liées aux hypothèses du modèle d'évaluation. Indépendamment de ces incertitudes liées au modèle, tous les résultats de l'évaluation militent en faveur de faibles prises pour faciliter le rétablissement du stock.

## INTRODUCTION

The basis and background for the delineation of management units of cod on Georges Bank and the vicinity were reviewed and summarized at the 2009 Eastern Georges Bank cod benchmark assessment meeting (O'Brien and Worcester 2009). For the purpose of a sharing agreement and consistent management by Canada and the USA, agreement was reached that the transboundary management unit for Atlantic Cod would be limited to the eastern portion of Georges Bank (DFO Statistical Unit Areas 5Zej and 5Zem; USA Statistical Areas 551, 552, 561 and 562) (DFO 2002). The management area is shown in Figure 1.

The 2015 assessment for the management unit of cod on Eastern Georges Bank (Figure 1) was updated using the 2013 benchmark model formulations (Claytor and O'Brien 2013). The assessment used Canadian and USA fishery information updated to 2014, including commercial landings and discards, the Fisheries and Oceans Canada (DFO) survey updated to 2015, the National Marine Fisheries Services (NMFS) spring survey updated to 2015, and the NMFS fall survey updated to 2014.

## FISHERY

## COMMERCIAL FISHERY CATCHES

Combined Canada/USA catches averaged 17,198 mt between 1978 and 1993, peaked at $26,463 \mathrm{mt}$ in 1982, and then declined to $1,683 \mathrm{mt}$ in 1995. They fluctuated around $3,000 \mathrm{mt}$ until 2004 and subsequently declined again. Catches in 2014 were 574 mt , including 30 mt of discards (Table 1; Figure 2). Catches included USA and Canadian discards in all years where discard estimates were available.

Canadian catches peaked at $17,898 \mathrm{mt}$ in 1982 and declined to $1,140 \mathrm{mt}$ in 1995 (Table 1; Figure 3). Since 1995, with lower cod quotas, the fishery has reduced targeting for cod through changes in fishing practices (Appendix A). From 1995-2013, Canadian catches fluctuated between 463 mt and $3,405 \mathrm{mt}$ (Table 1). In 2014, total Canadian catch (extracted landings on May 15, 2014, was 430 mt ), including discards, was 458 mt against a quota of 546 mt , taken primarily between June and December by otter trawl and longline (Figures 4 and 5). All 2014 landings were subject to dockside monitoring.
For the Canadian otter trawl fishery on Eastern Georges Bank, codend of 130 mm square mesh has been the standard mesh size since 1995. In 2014, a test project with alternative codend meshes of 125 mm square and 145 mm diamond was undertaken for the purpose of improving the catch rate of haddock and reducing cod bycatch relative to haddock catches. The test result was reported by Morin (2014).
For the Canadian groundfish fishery on Eastern Georges Bank, discard of cod are not permitted. From 1996 to 2014, the ratio of sums method, which uses the difference in ratio of cod to haddock from observed and unobserved trips, was applied to estimate discards of cod (Van Eeckhaute and Gavaris 2004; Hunt et al. 2005; Gavaris et al. 2006, 2007a; Clark et al. 2008). Cod discards from the 2014 Canadian groundfish fishery were estimated at 10 mt from the mobile gear and 3 mt from the fixed gear fishery (Table 1).
For the Canadian scallop fishery, landings until 1995 included those catches reported by the scallop fishery. Since 1996, the Canadian scallop fishery has not been permitted to land cod. The 3-month moving average observed discards rate has been applied to scallop effort to estimate discards of cod since 2005 (Gavaris et al. 2007b). In 2014, the estimated discards of cod by the Canadian scallop fishery were 15 mt (Table 1).

USA catches increased from 5,502 mt in 1978 to 10,550 mt in 1984 and subsequently fluctuated around 6,000 mt between 1985 and 1993 (Table 1; Figure 3). Since December 1994, under the more restricted fishery management measures (Appendix A), USA catches during 1994-2013 ranged between 39 mt and 1,204 mt . Total USA catch (landings and discards combined) was 116 mt for calendar year 2014 (Table 1; Figure 3). The majority of USA landings are usually taken by the second calendar quarter with the least amount landed during the third quarter (Figure 5). Otter trawl gear accounted for $96 \%$ and gillnet gear about 4\% of the landings during 2014.

Discards by USA groundfish fleets occur because of trip limits and minimum size restrictions. In July 2013, there was a reduction in the minimum size for the USA fishery from 22 inches to 19 inches. A ratio of discarded cod to total kept of all species (d:k) was estimated on a trip basis (Wigley et al. 2008). Total discards (mt) were estimated from the product of d:k and total commercial landings from the Eastern Georges Bank area. In the 2012 SAW55 cod benchmark meeting (NEFSC 2013), 'Delphi' determined mortality rates (otter trawl: 75\%) were applied to the final estimates of USA discards (Table 1). The estimated discards of cod in the groundfish fishery were 2 mt in 2014 (Table 1; Figure 3).

## SIZE AND AGE COMPOSITION

The size and age compositions of the 2014 Canadian groundfish fishery landings were derived from the pooled port and at-sea samples from all principal gears and seasons (Table 2; Figure 6). Landings by length peaked at 49 cm (19 in) for bottom trawlers and $64 \mathrm{~cm}(25 \mathrm{in})$ for longliners. Gillnetters caught fewer cod but these fish were larger, peaking at 73 cm (29 in) (Figure 7). The combined landings for all gears peaked at 49-61 cm (19-24 in) (Figure 8).

The size composition by length of cod discards from the 2014 Canadian scallop fishery was derived from at-sea sampling, and peaked at 34 cm (13 in) (Figure 7). The discards by length from the groundfish fishery were assumed to have the same size composition as the groundfish landings. The Canadian combined cod discards by length in 2014 from the groundfish and scallop fisheries peaked at 34 to 49 cm (13 to 19 in ) (Figure 8).
Otoliths taken from port samples were used for age determinations. Comparisons have indicated generally good agreement between DFO and NMFS age readers. (http://www.nefsc.noaa.gov/fbp/QA-QC/).
Catch at age composition was obtained by applying quarterly fishery age-length keys to the size composition. The age-length key from the 2014 DFO survey was used to augment the first quarter key.

The size and age compositions of the 2014 USA fishery landings on Eastern Georges Bank were estimated using port samples of length frequencies and age structures collected from all principal gears and seasons by market category (Wang et al. 2014). The age composition of the 2014 USA landings was estimated by market category by applying age-length keys to the size composition pooled by calendar quarter, semi-annually, or annually depending on the number of available length samples. The USA sampling protocol is one sample per 100 mt of landings (i.e., where 1 length sample $=100$ fish and 1 age sample $=20-25$ fish). The 2014 age-length keys were supplemented with age samples from statistical areas 522 and 525 for the catch at age calculations. Landings by length in 2014 peaked at $53-59 \mathrm{~cm}$ (21-23 in) (Figure 9).

The size and age composition of discarded fish were estimated using at-sea observer samples of length frequency and commercial and NMFS survey age keys from the same area and season. Discards in 2014 peaked at 47 cm (19 in) (Figure 9).

The 2014 total catch composition of combined landings and discards for Canada and the USA is shown in Figure 10. Canadian catches by length peaked at 49-61 cm (19-24 in); and USA catches by length peaked at 53-59 cm (21-23 in).

The 2014 combined Canada/USA landings and discards fishery age composition, by number, was the highest for the 2010 year class at age 4 (43\%), followed by the 2011 year class at age $3(35 \%)$ and the 2009 year class at age 5 (12\%) (Table 3; Figure 11). By weight, the 2010 year class dominated the 2014 fishery ( $47 \%$ ) followed by the 2011 ( $31 \%$ ) and 2008 year classes (9\%) (Figure 11). The contribution of age 7 and older fish continued to be small in recent years, $0.2 \%$ by number and $1 \%$ by weight in 2014 (Table 3; Figure 12).

Fishery weights at age showed a declining trend starting in the early 1990s (Table 4; Figure 13). Compared to 2013, the weights at age in 2014 improved for ages 3,7 and 8, but still at lower levels.

## ABUNDANCE INDICES

## RESEARCH SURVEYS

Surveys of Georges Bank have been conducted by DFO each year (February/March) since 1986 and by NMFS each spring (April) since 1968 and each fall (October) since 1963. All surveys use a stratified random design (Figures 14 and 15). Most of the DFO surveys have been conducted by the CCGS Alfred Needler using a Western IIA trawl. A sister ship, the CCGS Wilfred Templeman, conducted the survey in 1993, 2004, 2007, and 2008. No conversion factors are available for the Templeman, however, this vessel is considered to be similar in fishing strength to the Needler. For the NMFS surveys, two vessels have been employed and there was a change in the trawl door in 1985. Vessel and door type conversion factors derived experimentally from comparative fishing have been applied to the survey results to make the series consistent (Forrester et al. 1997). Additionally, two different trawl nets have been used on the NMFS spring survey, a modified Yankee 41 from 1973-81 and a Yankee 36 in other years, but no net conversion factors were available for cod. A new net and vessel (NOAA ship Henry B. Bigelow), with revised station protocols have been used to conduct the NMFS spring and fall surveys since 2009. Length calibration factors (Brooks et al. 2010) were applied to the NMFS spring and fall survey results since 2009 (Wang et al. 2014).
The spatial distribution of ages 3 and older cod caught during the 2014 NMFS fall, 2015 DFO and 2015 NMFS spring stratified random surveys (Wang et al. 2014; Figures 14 and 15) were similar to observations from those surveys over the previous decade, with most fish concentrated on the northeastern part of Georges Bank (Figures 16-18).
The catch in numbers from the 2015 DFO survey was somewhat higher than 2014, but still amongst the lowest in the time series (1986-2015) (Table 5). The 2011 year class at age 4 was $44 \%$ by number, followed by the 2013 year class at age 2 ( $27 \%$ by number) and the 2010 year class at age 5 ( $25 \%$ by number). There was no catch of the 2014 year class at age 1 and no catch of fish older than 7 (Table 5; Figure 19).
The 2015 NMFS spring survey catch decreased from 2014. Similar to the DFO survey, 2015 was among the lowest in the time series (Table 6). The 2010 year class at age 5 was dominant ( $40 \%$ by number), followed by the 2011 year class at age 4 ( $27 \%$ in number) and 2013 year class at age 2 ( $20 \%$ in number). There were no catch of fish older than 6 (Table 6; Figure 19).
The catch from the 2014 NMFS fall survey decreased from 2013, below the average of the time series. There was one big tow, which contributed $48 \%$ to the total catch. The 2010 year class at age 4 was $32 \%$ by number, followed by the 2011 year class at age 3 ( $21 \%$ by number). The 2013 year class at age 1 accounted for $21 \%$ by number (Table 7; Figure 19).

The coefficient of variation (CV) of stratified mean catch number per tow for the three surveys is shown in Tables 8-10 and Figure 20. Median CV values indicated the most variable catch being the ages 1 and 8 for the DFO survey, ages 7 and 8 for the NMFS spring survey, and ages 1 and 5 for the NMFS fall survey. The CVs were similar between the DFO and NMFS spring survey values and smaller compared to the NMFS fall survey values. The catch from all three surveys became more variable after mid-1990s, which might be caused by patchy distribution of cod at low abundance.

The survey abundance at age shows poor recruitment since the 1990 year class in all three surveys and representation of older ages in recent years were poor (Tables 5-7; Figure 19).

For the survey swept area biomass, both the 2014 NMFS fall survey and 2015 NMFS spring survey biomass decreased from last year; the 3 surveys were among the lowest in the time series (Table 11; Figure 21).

The number weighted average weights at age derived from the DFO survey and NMFS spring survey were used to represent the population weight at age for the beginning of the year. All the weights at age display a declining trend since the early-1990s (Table 12; Figure 22).

Fulton's condition factor (K), an indicator that uses observed weight and length to measure fish condition, was calculated using the data from all three surveys. It showed notable downward trends in recent years from the DFO survey samples and NMFS spring survey samples (Figure 23), although the NMFS spring survey does show an increasing trend since 2011. There were limited catches from the NMFS fall survey (Table 7). The trend from those samples was not clear (Figure 23).

The total mortality ( $Z$ ) was calculated by two age groups (ages 4 and 5 and ages 6 to 8 ) using DFO survey and NMFS spring survey abundance indices, separately. It showed that Z of ages 4 and 5 has been lower than the older age group (Figure 24). $Z$ has been high throughout the assessment time period for both age groups (Figure 24) and increasing in recent years, although relative $F$ (fishery catch at age per survey abundance indices) declined significantly since the mid-1990s (Figure 25).

## ESTIMATION AND DIAGNOSTICS

## CALIBRATION OF VIRTUAL POPULATION ANAYSIS (VPA)

At the benchmark assessment review in 2013 there was no consensus on a benchmark model, however, the TRAC did agree to provide catch advice based on a virtual population analysis (VPA) "M 0.8 " model, in conjunction with a consequence analysis that compares the VPA and ASAP model (presented below) projection results (Claytor and O'Brien 2013). The VPA used fishery catch statistics and size and age composition of the catch from 1978 to 2014 (including discards). The adaptive framework, ADAPT (Gavaris 1988), was used for calibrating the VPA with trends in abundance from three research bottom trawl survey series: DFO, NMFS spring and NMFS fall. Computational formulae used in ADAPT are described in Rivard and Gavaris (2003a).
In this model, natural mortality (M) was assumed equal to 0.2, except for ages 6+ from 1994 onwards where M was fixed at 0.8 . The data used in the model were:
$C_{a, t}=$ catch at age for ages $a=1$ to $10+$ and time $t=1978-2014$, where $t$ represents the year during which the catch was taken.
$I_{1, a, t}=$ DFO survey for ages $a=1$ to 8 and time $t=1986.17,1987.17 \ldots$ 2014.17, 2015.00.
$I_{2, a, t}=$ NMFS spring survey (Yankee 41) for ages $a=1$ to 8 and time $t=1978.28,1979.28$, 1980.28, 1981.28.
$I_{3,, a, t}=$ NMFS spring survey (Yankee 36) for ages $a=1$ to 8 and time $t=1982.28,1983.28 \ldots$ 2014.28, 2015.00.
$I_{4, \mathrm{a}, t}=$ NMFS fall survey for ages $\mathrm{a}=1$ to 5 and time $t=1978.69,1979.69 \ldots 2013.69$, 2014.69.
The population was calculated to the beginning of 2015; therefore the DFO and NMFS spring survey indices for 2015 were designated as occurring at the beginning of the year (i.e., 2015.00). The benchmark formulations assumed that observation errors for the catch at age data were negligible. Observation errors for the abundance indices at age were assumed to be independent and identically-distributed after taking natural logarithms of the values. Zero observations for abundance indices were treated as missing data, as the logarithm of zero is not defined. Fishing mortality on age 9 for 1978-2013 was assumed to be equal to the population weighted average fishing mortality on ages 7 and 8 . The population abundance at age 9 in 2014 was estimated, as there were no age 9 cod caught in the fishery in 2014. The benchmark VPA formulation did not provide specific guidance on how to address this situation, so this represents a change from previous years.

Estimation was based on minimization of the objective function:
$\sum_{s, a, t}\left(\ln I_{s, a, t}-\left(\hat{\kappa}_{s, a}+v_{a, t}\right)\right)^{2}$
where $s$ indexes survey. The estimated model parameters were:
$v_{\mathrm{a}, \mathrm{t}}=\ln N_{\mathrm{a}, \mathrm{t}}=\ln$ population abundance for ages $\mathrm{a}=2$ to 9 at beginning of 2015; age 9 in 2014.
$K_{1, a}=\ln$ DFO survey catchability for ages $\mathrm{a}=1$ to 8 at time $\mathrm{t}=1986-2015$
$K_{2, a}=\operatorname{In}$ NMFS spring survey (Yankee 41) catchability for ages $a=1$ to 8 at time $t=1978$-1981.
$K_{3, a}=\ln$ NMFS spring survey (Yankee 36) catchability for ages $a=1$ to 8 at time $t=1982-2015$.
$K_{4, a}=\ln$ NMFS fall survey catchability for ages $a=1$ to 5 at time $t=1978-2014$.
Statistical properties of the estimators were determined using conditional non-parametric bootstrapping of model residuals (Efron and Tibshirani 1993; Rivard and Gavaris 2003a).

For the beginning of 2015, the population abundance estimate of the 2013 year classes at age 2 exhibited the largest relative bias of $14 \%$ and relative error of $56 \%$. The relative bias for other ages ranged between $1 \%$ and $8 \%$ and the relative error ranged between $45 \%$ and $31 \%$ (Table 13). The population abundance of the 2005 year class at age 9 in 2014 was estimated as 0.09 million, with relative bias of $1 \%$ and relative error of $24 \%$. Survey catchability (q) at age progressively increased until age 4 for DFO survey and NMFS spring survey (Figure 26). Survey catchability at age for the NMFS fall survey was very low (Figure 26).

The overall fit of model estimated biomass to the DFO, NMFS spring and NMFS fall surveys was generally consistent with the survey trends after 1994 (Figure 27). There were residual patterns that suggested obvious year effects (Figure 28). Average fishing mortality (F4-9) by time blocks for 1978-1993, 1994-2009 and the recent 5 years 2010-2014 was 0.48, 0.27 and 0.08 , respectively. The temporal trend of fishing mortality was consistent with fishery management effort trend. The fishery partial recruitment (PR) started to show a dome-shape in the most recent 5 -year period (Figure 29). In contrast, there was relatively flat fishery PR pattern for the earlier two time periods, except for the age 10+ group (Figure 29).

Retrospective analysis was used to detect any bias of consistently overestimating or underestimating fishing mortality, biomass, or recruitment relative to the terminal year estimates. At the 2013 benchmark meeting, the VPA "M 0.8 " model with catch data through 2011 did not show any retrospective pattern (Claytor and O'Brien 2013), suggesting that the model assumptions on natural mortality were appropriate and that the fishery catch at age was
consistent with the survey indices. However, in the 2013 assessment, with catch data through 2012 (Wang and O'Brien 2013a), the 2003 year class was estimated to be substantially smaller than the estimate from the 2013 benchmark model formulation with one less year of data. In the 2013 assessment, the 2003 year class was estimated at 4.1 million at age 1 compared to the benchmark estimate of 13.5 million, with one less year of data (Figure 30). The estimate was 4.4 million in the 2015 (Table 15) and 2014 assessments, close to the 2013 assessment (Wang et al. 2014). In the retrospective analysis, the 2015 assessment results were very close with the 2014 and 2013 assessment. The average Mohn's rho was calculated for the seven retrospective relative differences in assessment years 2009-2015. The values for Mohn's rho were 0.5 for SSB, -0.34 for F , and -0.24 for age-1 recruitment (Table 14).

Possible reasons for the appearance of a retrospective bias after adding one more year of data were explored in the 2013 and 2014 assessments (Wang and O'Brien 2013a; Wang et al. 2014). One reason could be error in the fishery catch which caused low catch of the 2003 year class at age 9 in 2012 or, consequently, error which caused high catch of the 2003 year class at the younger ages (3-6). Another possible reason might be the actual natural mortality experienced by the 2003 year class between ages 8 and 9 was higher than the assumed $\mathrm{M}=0.8$ (Z>>1 from surveys using catch curve analysis). Using the assumed natural mortality would artificially reduce the abundance of the entire 2003 cohort in the backward calculation (even if the 0.8 is a good approximation of M among ages 6 and 7).

In the 2013 and 2014 assessment, sensitivity runs were conducted to explore the uncertainties in estimation of the 2003 year class (Wang and O'Brien 2013a; Wang et al. 2014). The sensitivity analyses suggested that the low estimate of the 2003 year class may be an outlier, which then caused a retrospective bias in the 2013 and 2014 assessment. The " M 0.8 " model got very similar population abundance estimates of other year classes in the terminal year or recruitments in other years when the effect of the 2003 year class was removed from the objective function by removing the 2003 year class abundance indices. Also the bias in the estimate of the 2003 year class had little impact on projection in the 2013 and 2014 assessment (Wang and O'Brien 2013a; Wang et al. 2014).
Fixing the retrospective bias could be done using the "est 2003yc" model (Figure 31). In this sensitivity run, the 2003 year class at age 9 was estimated in the model for the terminal year of 2013, 2014 and 2015, respectively. The average Mohn's rho was calculated for the seven retrospective relative differences in years 2009-2015. The values for Mohn's rho were 0.08 for SSB, 0.04 for $F$, and -0.23 for age-1 recruitment (Table 14).
Applying the Mohn's rho adjustment was thought not to be appropriate and was not conducted in this assessment. Residuals of the 2003 year class from the three surveys were predominantly positive, which means that the 2003 year class was underestimated in the 2013, 2014 and 2015 assessment from the " M 0.8 " model (Figure 32). Mohn's rho adjustment would further underestimate the biomass. The sensitivity analysis in the 2013 and 2014 assessment illustrated the terminal year population abundance estimate and projection from the VPA "M 0.8 " model is robust to the uncertainties in the estimate of the 2003 year class.

## STATE OF RESOURCE

The estimates presented below were from the 2015 VPA "M 0.8" model (Tables 15-17).
Adult population biomass (ages 3+) declined substantially from about 52,000 mt in 1990 to below $16,000 \mathrm{mt}$ in 1995, the lowest observed at that time (Table 14; Figure 33). Biomass has subsequently fluctuated between $5,900 \mathrm{mt}$ and $18,800 \mathrm{mt}$. The estimate of age 3+ biomass was $10,048 \mathrm{mt}$ ( $80 \%$ confidence interval: 8,272-12,579 mt) at the beginning of 2015 (Table 14). The increase of age $3+$ biomass during 2005-2009 was largely due to the recruitment and growth of the 2003 year class and, since 2011, was largely due to the recruitment and growth of the 2010
year class (Figure 34). High natural mortality, lower weights at age in the population in recent years and generally poor recruitment have contributed to the lack of sustained rebuilding. Survey biomass indices have been lower since the mid-1990s (Figure 21). The estimated adult population biomass at the beginning of 2015 from the VPA was about one-fifth of the 1978 biomass (Figure 33).

Recruitment at age 1 has been low in recent years (Table 19; Figure 33). Since 2000, the 2003 year class at 4.4 million fish at age 1 ( 13.5 million fish at age 1 from the 2012 assessment) had been the highest recruitment estimated. The current estimate of the 2010 year class at age 1 is 4.3 million, which is close the 2003 year class based on the 2015 assessment. Both the 2003 and 2010 year classes are around half of the average (about 11 million age 1 fish) during 19781990 when the productivity was considered to be higher (Table 15; Figure 33). Recruitment for the 2002, 2004, 2008 and 2012 year classes are the lowest on record. The current biomass is well below $30,000 \mathrm{mt}$, above which there is expected to be a better chance for higher recruitment (Figure 35).

Fishing mortality (population number weighted average of ages 4-9) was high prior to 1994 (Table 16; Figure 36). F declined in 1995 to $F=0.11$ due to restrictive management measures. $F$ in 2014 was estimated to be 0.04 ( $80 \%$ confidence interval: $0.035-0.058$ ). The assessment showed that $F$ has been declining since 2007 and has been at or below $F=0.11$ since 2011 .

## PRODUCTIVITY

Recruitment, natural mortality, age structure, fish growth and spatial distribution typically reflect changes in the productive potential. While management measures have resulted in a decreased exploitation rate since 1995 (Figure 25), total mortality has remained high and adult biomass has fluctuated at a low level. The current biomass is well below $30,000 \mathrm{mt}$; when biomass is above this threshold there is a better chance for higher recruitment (Figure 35). Average weight at length, used to reflect condition, has been stable in the past, but has started to decline in recent years. Size at age in the 2014 fishery remains low for most age groups (Table 4; Figure 13). The research survey spatial distribution patterns of adult (age $3+$ ) cod have not changed over the past decade (Figures 16-18). High natural mortality of age $6+$, low weights at age in the population in recent years and poor recruitment have contributed to the lack of rebuilding.

## HARVEST STRATEGY

The Transboundary Management Guidance Committee (TMGC) has adopted a strategy to maintain a low to neutral risk of exceeding the fishing mortality reference. At the 2013 benchmark meeting, it was agreed that the current $F_{\text {ref }}=0.18$ (TMGC meeting in December 2002) is not consistent with the VPA "M 0.8 " model, and a lower value for $F_{\text {ref }}$ would be more appropriate (Claytor and O'Brien 2013). At the 2014 TRAC meeting, it was agreed that $F=0.11$ was an appropriate fishing reference point for the VPA "M 0.8 " model based on the analyses presented (O'Brien and Worcester 2014). This value was derived from an age-disaggregated Sissenwine-Shepherd production model using M = 0.8 (Wang and O'Brien 2013b). TRAC recommends basing catch advice on $F=0.11$. When stock conditions are poor fishing mortality rates should be further reduced to promote rebuilding.

## OUTLOOK

This outlook is provided in terms of consequences with respect to the harvest reference points for alternative catch quotas in 2016 and 2017 (Gavaris and Sinclair 1998; Rivard and Gavaris 2003b).

Uncertainty about current biomass generates uncertainty in forecast results, which is expressed here as the probability of exceeding $F=0.11$ in 2016 and 2017, as well as the change in adult biomass from 2016 to 2017 and from 2017 to 2018. The risk calculations assist in evaluating the consequences of alternative catch quotas by providing a general measure of the uncertainties. However, risk calculations are dependent on the data, and model assumptions and do not include uncertainty due to variations in weight at age, PR to the fishery, natural mortality, systematic errors in data reporting or the possibility that the model may not reflect stock dynamics closely enough.

For projections, the average of the most recent three years of fishery and survey weights at age is used for fishery and beginning year population biomass for 2015-2017. The 2015-2017 PR is based on the most recent five years of estimated PR (Table 18). The 2010-2014 average recruitment at age 1 is used for 2015-2018 projections. The uncertainties for this estimate are not reflected in the projection.

## 2016 PROJECTION AND RISK ANALYSIS

Assuming a 2015 catch equal to the 650 mt total quota, both deterministic (Table 19) and stochastic (Table 20; Figure 37) projections based on F reference point 0.11 are provided. In 2016, a $50 \%$ risk of not exceeding $F=0.11$ corresponds to catches of 675 mt . Catches of 600 mt correspond to a lower (25\%) risk (Table 20; Figure 37). Even with no fishing in 2016, there is a greater than $50 \%$ risk of a decrease in adult biomass from 2016 to 2017. A catch of 475 mt would result in at least a $75 \%$ risk that 2017 adult biomass would decrease (Figure 37).

## 2017 PROJECTION AND RISK ANALYSIS

Assuming a 2015 catch equal to the 650 mt total quota and 2016 fishing mortality equal to 0.11 , the deterministic projection for 2017 is shown in Table 19. In 2017, a $50 \%$ risk of not exceeding $\mathrm{F}=0.11$ corresponds to catches of 725 mt . Catches of 640 mt correspond to a lower ( $25 \%$ ) risk (Table 20; Figure 38). A catch of 625 mt will result in a neutral risk ( $50 \%$ ) risk that 2018 age $3+$ biomass will be lower than 2017. A catch of 225 mt has a lower ( $25 \%$ ) risk (Figure 38).
A sensitivity risk analysis was conducted with an assumed 2016 catch equal to 600 mt , which has a $25 \%$ risk of exceeding $F=0.11$. In 2017, a $50 \%$ risk of not exceeding $F=0.11$ corresponds to catches of 750 mt , and catches of 650 mt corresponds to a lower ( $25 \%$ ) risk (Table 20; Figure 39). A catch of 575 mt will result in a neutral ( $50 \%$ ) risk that 2018 age 3+ biomass will be lower than 2017. A catch of 175 mt has a lower ( $25 \%$ ) risk (Figure 39).

## ERRORS DISCOVERED IN THE STOCHASTIC PROJECTION

For the stochastic projection in the software of ADAPT (Gavaris 1988), the exploitation rate on fully-recruited age groups calculated from the consequence of alternative catch quota options is compared with the exploitation rate reference point ( $\mathrm{U}_{\text {ref }}$ ), instead of fishing mortality comparison with fishing mortality reference point ( $\mathrm{F}_{\text {ref }}$ ). Uref is a function of natural mortality and $F_{\text {ref. }}$. If the natural mortality is constant across ages there is no difference when an exploitation rate reference ( $\mathrm{U}_{\text {ref }}$ ) or fishing mortality reference point ( $\mathrm{F}_{\text {ref }}$ ) is used. However, if the natural mortality varies with ages the $\mathrm{U}_{\text {ref }}$ would be different across ages even if $\mathrm{F}_{\text {ref }}$ is the same for all the ages.

During the TRAC, it was discovered that the age-specific difference in natural mortality ( $\mathrm{M}=0.2$, except $M=0.8$ for ages $6+$ ) was not accounted for in calculations of Uref in the stochastic projections for the VPA " $\mathrm{M}=0.8$ " model. The stochastic projection was undertaken using $\mathrm{U}_{\text {ref }}=7 \%$, a value calculated from ages $6+$ natural mortality ( $\mathrm{M}=0.8$ ) and $\mathrm{F}_{\text {ref }}=0.11$ (Table 20a), while $\mathrm{U}_{\text {ref }}=10 \%$ if calculated from natural mortality of younger fish ( $\mathrm{M}=0.2$ ) and $F_{\text {ref }}=0.11$. This difference was not noticed in the past assessments due to the flat fishery PR,
but given differences in the PR between younger and older fish this year (Figure 29), the misaccounting of the two Uref values has become more apparent.

Considering the current ADAPT software does not incorporate the age-variant $\mathrm{U}_{\text {ref }}$ in the stochastic projection, it was agreed that this year's assessment should not attempt re-analysis. A sensitivity run with the $U_{\text {ref }}=10 \%$, a value derived from natural mortality of younger fish ( $M=0.2$ ) and $F_{\text {ref }}=0.11$, was conducted. It should be noted that although $U_{\text {ref }}=10 \%$ is appropriate for the younger fish, it would be overfishing for the older fish if there is a flat PR. In 2016, a $50 \%$ risk of not exceeding F = 0.11 corresponds to catches of 875 mt . Catches of 775 mt correspond to a lower (25\%) risk (Figure 40). In 2017, a 50\% risk of not exceeding $\mathrm{F}=0.11$ corresponds to catches of 950 mt . Catches of 825 mt correspond to a lower ( $25 \%$ ) risk (Figure 40).

Although the specific implications of this could not be evaluated at TRAC, it was noted that the deterministic projection (with the correct calculation that accounted for the age differences in M ) produced a 2016 catch of 842 mt . Generally, deterministic projection and the $50 \%$ risk of not exceeding $F_{\text {ref }}$ in the stochastic projection result in very similar estimates of catch. On this basis, the TRAC agreed that a revised stochastic risk analysis would likely result in an increase in the calculated catch on the order of 100-200 mt (Tables 19 and 20). Given this uncertainty, and due to the current status of the stock, the TRAC recommends that the risk calculations provided remain appropriate despite the unaccounted for age-specific difference in the stochastic projections.

## CONSEQUENCE ANALYSIS (RISKS ASSOCIATED WITH 2016-2017 PROJECTED CATCH)

A consequence analysis to understand the risks associated with assumptions of the VPA "M 0.8 " and ASAP "M 0.2 " models (Appendix B) was examined. This consequence analysis shows (Table 21):

1. the projected catch (ages $1+$ ) at $\mathrm{F}_{\text {ref }}=0.18$ and $\mathrm{F}=0.11$ and percent change in biomass, as if each model represented the "true state" of the resource; and
2. the consequences to fishing mortality and expected biomass (ages $3+$ ) when 'true state' catch levels are removed under the assumptions of the other "alternate state" model.
In 2016, a catch of 675 mt at $\mathrm{F}=0.11$ would result in a decrease in the 2017 biomass of $6 \%$ in the VPA "true state" and an increase of $21 \%$ in the ASAP "alternate state". A catch of 223 mt at $F_{\text {ref }}=0.18$ would result in a $42 \%$ increase in the 2017 biomass based on the ASAP "true state", but a decrease of $2.8 \%$ based on the VPA "alternate state".

In 2017, a catch of 725 mt at $\mathrm{F}=0.11$ would result in a decrease in the 2017 biomass of $0.6 \%$ in the VPA "true state" and an increase of $31 \%$ in the ASAP "alternate state". A catch of 304 mt at $F_{\text {ref }}=0.18$ would result in a $40 \%$ increase in the 2017 biomass based on the ASAP "true state", but a decrease of $2.7 \%$ based on the VPA "alternate state".

## SPECIAL CONSIDERATIONS

Table 22 summarizes the performance of the management system. It reports the TRAC advice, TMGC quota decision, actual catch, and realized stock conditions for this stock.

Fishing mortality and trajectory of age 3+ biomass from the assessment following the catch year are compared to results from this assessment. These comparisons were kindly provided in 2011 by Tom Nies (staff member of the New England Fishery Management Council, NEFMC) and updated for this assessment. The inconsistency of TRAC advice in the past, with the realized stock conditions from the recent assessment, was mainly due to assessment model changes
following the 2009 benchmark assessment. Further, the retrospective bias in the assessment also accounted for part of this inconsistency.

The consequence analysis reflects the uncertainties in the assessment model assumptions. Considering the current poor stock conditions, despite these uncertainties, all assessment results indicate that low catches are needed to promote rebuilding.
Discovery that the calculation being made in the risk analysis for the VPA results did not account for the differences in natural mortality rate between young ages and ages 6+ could have impacted catch advice since 2009. The TRAC compared deterministic and stochastic projections results for assessments since 2009 and found that the differences were minimal (-11-7\%) until 2015 (20\%) (Table 23).

## ACKNOWLEDGEMENTS

We thank J.R. Martin for providing the Canadian discards data, B. Hatt of DFO and N. Shepherd of NMFS for providing ageing information for the DFO and NMFS surveys and Canadian and USA fisheries, G. Donaldson and D. Frotten of DFO and at-sea observers from Javitech Ltd. for providing samples from the Canadian fishery.

Table 2. Length and age samples from the USA and Canadian fisheries on Eastern Georges Bank. For Canadian fisheries, at-sea observer samples are included since 1990. The first quarter age samples are supplemented with USA fishery age samples from 5Zjm for 1978-1986 and DFO survey age samples for 1987-2014; the numbers are shown in brackets. The highlighted numbers include samples from western Georges Bank.

| Year | USA |  | Canada |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Lengths | Ages | Lengths | Ages |
| 1978 | 2,294 | 384 | 7,684 | 1,364 |

Table 11. Swept area biomass (mt) for Eastern Georges Bank cod from the NMFS Fall, NMFS Spring and DFO surveys. Conversion factors to account for vessel and trawl door changes have been applied, including the biomass conversion factor of 1.58 used for the vessel Henry B. Bigelow since 2009. The DFO survey began in 1986, indicated by a dash (-) in that column prior to 1986. The dash (-) in the data cell for 2015 fall NMFS survey indicates that this survey had not yet occurred.

Table 3. Beginning of year population biomass ( $m t$ ) for Eastern Georges Bank cod during 1978-2015 from the " M 0.8 " model formulation using the bootstrap bias adjusted population abundance at the beginning of 2015. The dash (-) at age 1 in 2015 indicates that age 1 in the final year is not estimated in the model.

| Year | Age |  |  |  |  |  |  |  |  |  |  |  |

Table 7. Projection and risk analysis result for Eastern Georges Bank cod from the "M 0.8 " model formulations: a) risk of fishery catch will exceed F reference point 0.11 in 2016 and 2017; and b) risk of ages 3+ biomass will not increase from 2016 to 2017 and from 2017 to 2018.
a)

| Probability | $\mathbf{0 . 2 5}$ | $\mathbf{0 . 5}$ | $\mathbf{0 . 7 5}$ |
| :---: | :---: | :---: | :---: |
| 2016 | 600 mt | 675 mt | 775 mt |
| $2017\left(\mathrm{~F}_{2016}=0.11\right)$ | 640 mt | 725 mt | 850 mt |
| $2017(2016$ catch $=600 \mathrm{mt})$ | 650 mt | 750 mt | 875 mt |

b)

| Probability | $\mathbf{0 . 2 5}$ | $\mathbf{0 . 5}$ | $\mathbf{0 . 7 5}$ |
| :---: | :---: | :---: | :---: |
| 2016 to 2017 | 0 mt | 0 mt | 475 mt |
| 2017 to $2018\left(\mathrm{~F}_{2016}=0.11\right)$ | 225 mt | 625 mt | $1,025 \mathrm{mt}$ |
| 2017 to $2018(2016$ catch $=600 \mathrm{mt})$ | 175 mt | 575 mt | $1,025 \mathrm{mt}$ |

Table 8. Consequence analysis of risks of different management actions taken for Atlantic Cod from Eastern Georges Bank. Projected catch and biomass are presented for each of two 'true state of nature' management models: VPA "M0.8" model with $F=0.11$ and ASAP $M=0.2$ model with $F_{\text {ref }}=0.18$ during 2016-2018 on the main diagonal ("true state"). The risks of the alternative management actions "alternate state" are on the counter diagonal (see text). Fishing mortality (F), January 1 stock biomass, and percent change in biomass ( $\% B$ ) from the previous year are presented for each projection.

## CONSEQUENCE ANALYSIS

| Catch 2014 <br> Quota 2015 | $\begin{aligned} & 574 \mathrm{mt} \\ & 650 \mathrm{mt} \end{aligned}$ |  |  |

Figure 19. Survey abundance at age (numbers) of Eastern Georges Bank cod. The bubble area is proportional to magnitude within each survey. Conversion factors to account for changes in door type, net and survey vessel were applied to the NMFS surveys. The NMFS spring survey was conducted using a modified Yankee 41 during 1978-1981 (pink bubbles). The 2003 year class is identified with green bubbles and the purple bubbles show the 2010 year class.

Figure 35. Relationship between adult biomass (ages 3+) and recruits at age 1 for Eastern Georges Bank cod. The red arrow indicate the 2010 year class at age 1.

Figure 36. Average fishing mortality rate at ages 4 to 9 and catches for Eastern Georges Bank cod. The established fishing mortality threshold reference, $F_{\text {ref }}=0.18$. The F reference point for the " $M 0.8$ " model is 0.11 .

Figure 37. Risk of 2016 fishing mortality exceeding F reference point 0.11 and 2017 biomass not increasing from 2016 for alternative total yields of Eastern Georges Bank cod from the "M 0.8" model formulation.

Figure 38. Assuming F2016 = 0.11, risk of 2017 fishing mortality exceeding F reference point 0.11 and 2018 biomass not increasing from 2017 for alternative total yields of Eastern Georges Bank cod from the "M 0.8" model formulation.

Figure 39. Assuming a catch of 600 mt in 2016, risk of 2017 fishing mortality exceeding F reference point 0.11 and 2018 biomass not increasing from 2017 for alternative total yields of Eastern Georges Bank cod from the "M 0.8" model formulation.

Figure 40. Risk of 2016 (left) and 2017 (right) fishing mortality exceeding F reference point 0.11 when $U_{\text {ref }}=10 \%$, a value $t$ calculated from $M=0.2$ and $F=0.11$, is used for alternative total yields of Eastern Georges Bank cod from the "M 0.8 " model formulation.

## APPENDICES

## APPENDIX A. MANAGEMENT HISTORY OF EASTERN GEORGES BANK COD FISHERY (1978-2014).

a) Canadian fishery management history of cod on Eastern Georges Bank, 1978 to 2014.

| Year | Canadian Management History |
| :---: | :---: |
| 1978 | Foreign fleets were excluded from the 200 mile exclusive economic zones of Canada and USA. |
| 1984 | October implementation of the maritime boundary between the USA and Canada in the Gulf of Maine Area. |
| 1985 | $5 Z$ cod assessment started in Canada; Set TAC; TAC $=25,000 \mathrm{mt}$. |
| 1986 | TAC $=11,000 \mathrm{mt}$ |
| 1987 | TAC $=12,500 \mathrm{mt}$ |
| 1988 | TAC $=12,500 \mathrm{mt}$ |
| 1989 | $\mathrm{TAC}=8,000 \mathrm{mt} ;$ 5Zjm cod assessment. |
| 1990 | Changes to larger and square mesh size; Changes from TAC to individual and equal boat quotas of 280,000 lbs with bycatch restrictions; Temporary Vessel Replacement Program was introduced. |
| 1991 | TAC = 15,000 mt; Dockside monitoring; Maximum individual quota holdings increased to $2 \%$ or 600t (whichever was less). |
| 1992 | TAC = 15,000 mt; <br> Introduction of ITQs for the OTB fleet. |
| 1993 | TAC $=15,000 \mathrm{mt}$, ITQ for the OTB fleet not based on recommended catch quotas; OTB $<65$ fleet was allowed to fish during the spawning season (March-May $31^{\text {st }}$ ). |
| 1994 | TAC $=6,000 \mathrm{mt}$, <br> Spawning closures January to May $31^{\text {st }}$; <br> Mesh size was 130 mm square for cod, haddock an Pollock for ITQ fleet; <br> Minimum mesh size of 6 " was required for gillnets; <br> Minimum fish size is 43 cm (small fish protocols) for cod, haddock an Pollock for ITQ fleet; OT> 65' could not begin fishing until July 1; <br> Fixed gear must choose to fish either $5 Z$ or 4 X during June $1^{\text {st }}$ to September $30^{\text {th }}$. |
| 1995 | TAC $=1,000 \mathrm{mt}$ as a bycatch fishery; <br> January $1^{\text {st }}$ to June $18^{\text {th }}$ was closed to all groundfish fishery; <br> 130 mm square mesh size for all mobile fleets; <br> Small fish protocols continued; <br> $100 \%$ dock side monitoring; <br> Fixed gear vessels with a history since 1990 of 25 mt or more for 3 years of cod, Haddock, Pollock, hake or Cusk combined can participate in $5 Z$ fishery. |
| 1996 | TAC = 2,000 mt; <br> Prohibition of the landing of groundfish (except monkfish) by the scallop fishery; <br> ITQ vessel require minimum 130 mm square mesh for directed cod, Haddock and Pollock trips; <br> Small fish protocols continued; <br> For community management, quota allocation of each fixed gear based on catch history using the years 1986-1993; <br> $100 \%$ mandatory dockside monitoring and weighout. |
| 1997 | TAC $=3,000 \mathrm{mt}$ |
| 1998 | TAC $=1,900 \mathrm{mt}$ |
| 1999 | TAC = 1,800 mt; Mandatory cod separator panel when no observer on board; January and February mobile gear winter Pollock fishery. |
| 2000 | TAC = 1,600 mt; January and February mobile gear winter Pollock fishery. |
| 2001 | TAC $=2,100 \mathrm{mt}$ |

| Year | Canadian Management History |
| :---: | :---: |
| 2002 | TAC $=1,192 \mathrm{mt}$ |
| 2003 | TAC $=1,301 \mathrm{mt}$ |
| 2004 | TAC = 1,000 mt; Canada-USA resource sharing agreement on Georges Bank. |
| 2005 | TAC = 740 mt ; <br> Exploratory winter fishery January to February 18, 2005; Spawning protocol: $25 \%$ of maturity stages at 5 and 6 . |
| 2006 | TAC = 1,326 mt; <br> Exploratory winter fishery January to February 6, 2006; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2007 | TAC = 1,406 mt; <br> Exploratory winter fishery January to February 15, 2007; <br> High mobile gear observer coverage (99\%); <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2008 | TAC = 1,633 mt; <br> Winter fishery from January $1^{\text {st }}$ to February 8, 2009; <br> At-sea observer coverage $38 \%$ by weight of the mobile gear fleet landings and $21 \%$ by weight of the fixed gear landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2009 | TAC = 1,173 mt; <br> Winter fishery from January 1 to February 21, 2009; <br> At-sea observer coverage $23 \%$ by weight of the mobile gear fleet landings and $15 \%$ by weight of the fixed gear landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2010 | TAC = 1,350 mt; <br> Winter fishery from January 1 to February 8, 2010; <br> At-sea observer coverage $18 \%$ by weight of the mobile gear fleet landings and $6 \%$ by weight of the fixed gear landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2011 | TAC = 1,050 mt; <br> Winter fishery from January 1 to Februay 5, 2011; <br> At-sea observer coverage $19 \%$ by weight of the mobile gear fleet landings, $20 \%$ by weight of the fixed gear landings and $3 \%$ by weight of the gillnet fleet landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2012 | TAC = 513 mt ; <br> Winter fishery from January 1 to February 6, 2012; <br> At-sea observer coverage $42 \%$ by weight of the mobile gear fleet landings, $26 \%$ by weight of the fixed gear landings and $35 \%$ by weight of the gillnet fleet landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2013 | TAC = 504 mt ; <br> Winter fishery from January 1 to February 3, 2013; <br> At-sea observer coverage $78 \%$ by weight of the mobile gear fleet landings, $29 \%$ by weight of the fixed gear landings and $19 \%$ by weight of the gillnet fleet landings; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |
| 2014 | TAC = 546 mt ; <br> Winter fishery from Januaryt 1 to February 9, 2014: <br> A test project with alternative codend meshes of 125 mm square and 145 mm diamond for the purpose of imporving the catch rate of haddock and reducing cod bycatch relative to haddock catched; <br> Spawning protocol: $30 \%$ of maturity stages at 5 to 7 . |

b) USA fishery management history of cod on Eastern Georges Bank, 1978 to 2014.

| Year | USA Management History |
| :---: | :---: |
|  | Regulatory Actions |
| 1953 | ICNAF era |
| 1973-1986 | TAC implemented for Div. $5 Z$ cod; 35,000/year |
| 1977 | Groundfish Fishery Management Plan (FMP Magnuson-Steveson Conservation management Act (MSCMA) |
| 1982 | Interim FMP |
| 1984 | Hague Line implemented |
| 1985 | Multi-species FMP |
| 1989 | Amendment 2 |
| 1994 | Emergency Rule - December year-round closures in effect |
| 1994 | Amendment 5; Days at Sea (DAS) monitoring; Mandatory reporting; Vessel Trip Reports (VTR) Amendment 6 |
| 1996 | Amendment 7; accelerated DSA reduction Sustainable Fisheries Act (SFA) |
| 1999 | Amendment 9 |
| 2002 | Interim rule; 20\% reduction in DAS |
| 2004 | Amendment 13; further reduction in DAS; hard TAC on eastern Georges Bank haddock and cod Eastern US/CAN Area haddock Special Access Program (SAP) Pilot Program |
| 2005 | DAS vessels limited to one trip/month in eastern US/CAN Area until April $30^{\text {th }}$ Limited access DAS vessles required to use separator panel trawl in the area |
| 2006 | Haddock separator trawl or flounder net required in eastern US/CAN Area |
| 2008 | Eastern US/CAN Area access delayed until August ${ }^{\text {st }}$, except longline gear September - Ruhle trawl (eliminator trawl) allowed in eastern US/CAN Area |
| 2009 | November - Eastern US/CAN Area, trawl vessels required to use separator/Ruhle south 41-40N |
| 2010 | Amendment 16, Framework 44 implemented; Sector management; Prohibition on discarding legal size fish US/CAN Area: prohibition on discarding legal size fish |
|  | Common pool: $500 \mathrm{lbs} /$ day, $5,000 \mathrm{lbs} /$ trip |
| 2012 | US/CAN area open May $1^{\text {st }}$ for trawl gear: haddock separator, rhule or flounder trawl |
| 2015 | Inside US/CAN Georges Bank cod: common pool : $100 \mathrm{lb} / \mathrm{DAS}, 500 \mathrm{lb} /$ trip |
|  |  |
|  | Mesh Sizes (Inches) |

| 2011 | March - 3,000 lbs/day during April $500 \mathrm{lbs} /$ day after April in eastern Georges Bank area |
| 2012 | Common pool: Georges Bank cod $1500 \mathrm{lbs} / \mathrm{A}$ DAS up to $4500 \mathrm{lbs} /$ trip ; Handgear B $75 \mathrm{lb} /$ trip |
| 2013 | January $1^{\text {st. }}$ Common pool: Georges Bank cod 3000 Ibs/A DAS up to $30,000 \mathrm{lbs} /$ Trip ; Handgear B $125 \mathrm{lb} /$ trip |
| 2014 | Common pool closure: Georges Bank cod August 18 through to April 30, 2015 |
|  | Closures |
| 1970 | Area 1(A) and 2(B) March-April |
| 1972-1974 | Area 1(A) and 2(B) March-May |
| 1977 | Seasonal spawning closure |
| 1987 | Modify Closed Area I to overlap with haddock spawning area |
| 1994 | January Closed Area II expanded, closed January -May, Closed Area I closed to all vessels except sink gillnet <br> December Closed Area I and II closed year-round to all vessels |
| 1999 | Scallopers allowed limited access to Closed Area II |
| 2004 | May to December access to northern corner of Closed Area II and adjacent area to target haddock with separator trawl <br> October - eastern Georges Bank closed to multi-species DAS permits |
| 2005 | January - eastern US/CAN Area reopened <br> April - eastern US/CAN Area closed until April $30^{\text {th }}$ <br> August - eastern US/CAN area closed (Georges Bank cod TAC projected near 90\%) |
| 2006 | Eastern US/CAN haddock SAP delayed opening until August $1^{\text {st }}$ |
| 2007 | April $25^{\text {th }}$ - eastern US/CAN Area closed until April $30^{\text {th }}$ <br> June - eastern US/CAN Area closed to limited access multi-species TAC (due to cod catch) <br> October - eastern US/CAN Area open to limited access multi-species TAC <br> November - eastern US/CAN Area closes |
| 2008 | May - eastern US/CAN Area delayed opening until August $1^{\text {st }}$; <br> June - eastern US/CAN Area delayed opening until August $1^{\text {st }}$ for all gear (prevent catching $1^{\text {st }}$ quarter cod TAC) |
| 2009 | April $1^{\text {st }}$ - eastern US/CAN Area closed; May - eastern US/CA area sloced until August $1^{\text {st }}$ for trawl vessels |
| 2010 | Eastern US/CAN Area closed April $20^{\text {th }}$ to $30^{\text {th }}$, TAC harvested; May $1^{\text {st }}$ opening delayed untl August |
| 2011 | Eastern US/CAN Area closed from May-July for trawl gear (commonpool vessles only) |
| 2013 | Common pool closure: July $30^{\text {th }}$ to August $31^{\text {st }}$ for Geoges Bank cod |

# APPENEDIX B. 2015 STATISTICAL CATCH AT AGE (ASAP) MODEL UPDATE FOR EASTERN GEORGES BANK COD 

## INTRODUCTION

This assessment presents an update of the statistical catch at age model 'Age Structured Assessment Program' (ASAP) reviewed at the 2013 April Eastern Georges Bank cod benchmark model meeting. The ASAP model was not chosen by the TRAC as a benchmark model for stock status, however, the TRAC agreed to apply the ASAP model results in a consequence analysis (Table 21 above) of projection results to be provided to managers for catch advice.

The ASAP model for cod from Eastern Georges Bank (GB) is formulated as closely as possible to the NEFSC GB cod assessment, since the ASAP model was recently approved as the new benchmark model, replacing the VPA that had historically been applied (NEFSC 2013a; 2013b).
ASAP was used to derive estimates of instantaneous fishing mortality and stock size in 2014. A retrospective analysis was performed for terminal year fishing mortality, spawning stock biomass (SSB), and age 1 recruitment. Stochastic projections from model results provide estimated landings and SSB during 2016-2018.

## ASSESSMENT MODEL FORMULATION

## Model Description

ASAP, a forward projecting statistical catch at age model (Legault and Restrepo 1998), was applied in this assessment and can be downloaded from the NOAA Fisheries Toolbox (NFT, http://nft.nefsc.noaa.gov/). A brief description of the model can be found in the previous assessment (Wang et al. 2014) and, for further details, the reader is referred to the technical manual (Legault 2008).

## Data Input

Input to the ASAP model is the same as for the VPA 0.8 model, with two exceptions. The ASAP uses beginning year weight-at-age that is back-calculated from the mid-year catch weight-atage (Rivard 1982; see: Table B1) as in the NEFSC GB cod assessment, rather than using the weight estimated from an average of the DFO and NEFSC spring research survey weight-atage (Table 16 above). The ASAP also does not use the most recent terminal year +1 survey (e.g. DFO 2015 and NMFS 2015 surveys) in the estimation.

Natural mortality (M) was age and time invariant and assumed to be 0.2 , which had been applied in earlier assessments, prior to 2013, for cod from eastern GB (Wang and O'Brien 2012).

## Model Formulation

The ASAP model formulation (base_rivard) presented and reviewed at the June 2014 TRAC (Wang et al. 2014) was updated for the 2015 assessment. A multinomial distribution was assumed for both fishery catch at age and survey age compositions. The catch CV was set equal to 0.05 and the recruitment CV set equal to 0.5 , however, the recruitment deviations were set with lambda $=0$, so the deviations did not contribute to the objective function.

Both the fishery and survey selectivity was modeled as 'flat-topped'. For the fisheries, two selectivity blocks were modeled as single logistic from 1978-1993 and 1994-2014.

The effective samples size (ESS) of the catch and surveys were adjusted based on interpretation of 'lanelli' plots (McAllister and lanelli 1997). The input ESS is compared to the
model predicted ESS; an appropriate ESS is considered to be that which intersects the input ESS.

At the 2013 benchmark (O'Brien and Wang 2013) the CV for each survey was initially set at the value generated from the survey estimate of stratified mean number per tow (DFO STRANAL). The CVs averaged 0.31(0.15-0.66; DFO), 0.32 ( $0.13-0.83$; NMFS spring), and 0.47(0.24-0.88; NMFS fall). Further examination of the model fits to the survey indices resulted in adding the following constant to each survey CV vector: 0.25 (DFO), 0.3 (NMFS spring \#36), and 0.2 (NMFS fall), except the NMFS spring \#41, which was not adjusted. These same values were added during this 2015 update.

## Model Results

Model results, including the objective function (OF), components to the OF, the root mean square error (RMSE), computed from standardized residuals, SSB, fishing mortality ( $F$ ), recruitment estimates at age 1 and the Mohn's rho retrospective bias adjustments are summarized in Table B2 for all model runs conducted.

A bridge ASAP run was conducted to include several changes to the input data. These included a slight modification to the estimation of USA discards in 2013 with the application of an annual length frequency rather than one by half-year and minor changes to the database in 1998, 2009 and 2012. The Canadian discards from the scallop fishery were recalculated using the new standardization of fishing effort, and the 2013 catch at age was re-estimated using a new length weight relationship from 2013 monthly port samples.

A comparison of the differences between the 2013 ASAP model results (2014 run1) and the bridge run (2014 run2) resulted in minor changes in the diagnostics and in the estimation of biomass (Table B2).

## BASE 2014 ASAP

The bridge run was updated with 2014 catch estimates and survey data and the results (run 3) are described Table B2 and Figures B1-B12. Model diagnostics are very similar to last year's assessment (Wang et al. 2014). Patterns in residuals still persist in both the catch and in the surveys, although the patterning is less in the autumn survey (Figures B1-B8). The ESS is still appropriate for both catch and the surveys.

## Fishing Mortality, SSB, and Recruitment

Fully recruited F (unweighted; ages 5+) was estimated at 0.33 in 2014 (Table B3; Figure B9), a $24 \%$ decrease from 2013. SSB in 2014 was estimated at $2,248 \mathrm{mt}$, a $47 \%$ increase from 2013 (Table B3; Figures B9-B10). Recruitment (millions of age 1 fish) of the 2010 year class is estimated at 1.2 million, the 2012 year class is the smallest year class estimated at 0.275 million, and the 2013 year class is estimated at 1.1 million fish (Table B3; Figures B9-B10).

## Retrospective Analysis

A retrospective analysis was performed to evaluate how well the ASAP calibration would have estimated F, SSB and recruits at age 1 for seven years (2006-2012) prior to the terminal year, 2014. The pattern of overestimating SSB and underestimating $F$ relative to the terminal year persists in this assessment and there is a general pattern of underestimating recruitment relative to the terminal year estimate (Figure B11). The retrospective rho values, the average of the last 7 years of the relative retrospective peels, were 0.59 for SSB, -0.36 for $F_{5+}$, and -0.18 for recruitment. Applying a retrospective adjustment ((1/(1+rho)) * estimate) results in estimates for 2014 of $\mathrm{F}=0.58, \mathrm{SSB}=1,413 \mathrm{mt}$, and age 1 recruitment $=1.3$ million fish.

## Model Uncertainty - MCMC

A Monte Carlo Markov Chain (MCMC) simulation was performed to estimate uncertainty in the model estimates. Two MCMC chains of initial length of 5.0 million were simulated with every $2,500^{\text {th }}$ value saved. The trace of each chain's saved draws suggests relatively good mixing for both SSB and F (Figure B12). The lagged autocorrelations showed variable correlation with increased lag, with correlations $\leq 0.1$ beyond lag 0 for SSB and F. The 2014 SSB MCMC estimate of $2,247 \mathrm{mt}$ has a $90 \%$ probability interval ( PI ) of 1,664-3,068 mt, and the 2014 MCMC average $\mathrm{F}_{5+}=0.36$ has a $90 \% \mathrm{PI}$ of $0.26-0.52$.

## BIOLOGICAL REFERENCE POINTS

Yield per Recruit Analysis
A yield per recruit (YPR) analysis was conducted at the 2013 Eastern Georges Bank cod model benchmark meeting (O'Brien and Wang 2013) using the methods of Thompson and Bell (1934). Results of YPR analysis are presented below. The current negotiated Eastern Georges Bank cod $F$ reference point is $F_{\text {ref }}=0.18$ (December 2002 meeting; TMGC 2002). The current GB cod $\mathrm{F}_{\text {MSY }}$ proxy $=\mathrm{F}_{40 \%}=0.18$.

| F | value |
| :--- | ---: |
| F0.1 | 0.19 |
| Fmax | 0.43 |
| F30\% | 0.29 |
| F40\% | 0.19 |
| F2014, adj | 0.58 |

Eastern George Bank cod is not managed by biomass reference points, however, for background purposes, non-parametric estimates of Maximum Sustainable Yield (MSY) and SSB at MSY (SSB MSY ) based on $\mathrm{F}_{40 \%}$ were estimated (O'Brien and Wang 2013) using the 34-year time series mean recruitment ( 5.484 million age 1 fish), Y/R (1.22) and SSB/R (7.18) as:

$$
\begin{aligned}
& \mathrm{F}_{40 \%}=0.19, \\
& \mathrm{MSY}=6,677 \mathrm{mt}, \text { and } \\
& \text { SSB }_{\text {MSY }}=39,353 \mathrm{mt} .
\end{aligned}
$$

The yield per recruit analysis was not updated with the 2015 ASAP results.

## MSY Biological Reference Points

## Long-term Stochastic Projection

For the 2013 Eastern Georges Bank cod model benchmark meeting, long term (100 years) stochastic projections were run using the same input data as the YPR with $\mathrm{F}_{\text {ref }}=0.18$. Following the GB cod accepted assessment projection formulation (NEFSC 2013b), recruitment was estimated from a 2-stage cumulative distribution function (CDF) based on either 19 low estimates or 14 high estimates of age 1 recruitment. Based on a visual examination of the stock recruit plot (Figure B10), when SSB is less than15,000 mt recruitment is drawn from the low recruitment CDF, and when SSB is greater than $15,000 \mathrm{mt}$ then recruitment is drawn from the high recruitment CDF.
The long term projection provided the following non-parametric biomass reference points:

$$
\begin{aligned}
& \mathrm{F}_{\text {REF }}=0.18, \\

$$

## PROJECTIONS

Short term stochastic projections under $\mathrm{F}_{40 \%}$ were performed from the updated 2014 ASAP model results to estimate landings and SSB during 2016-2017. The input values for mean catch and stock weights and PR were estimated as 3-year averages from 2012-2014. Maturity is assumed to be knife-edge at $100 \%$ for ages $3+$. Recruitment was estimated using the 2 -stage CDF described above and associated with a SSB breakpoint of $15,000 \mathrm{mt}$. Catch in 2015 was estimated based on the assumption that the 2015 quota of 650 mt would be caught. Bootstrapped starting values were adjusted for retrospective bias by applying the SSB rho factor of 0.59 to derive the adjustment factor of 0.629 .

The results of the adjusted short term projections indicate under the $\mathrm{F}_{\text {ref }}=0.18$ catch is projected to decrease in 2016 and then increase in 2017. SSB is projected to decrease in 2015, and then increase in 2016 and again in 2017.

| Year | SSB | F | Catch |
| ---: | ---: | ---: | ---: |
| 2015 | 1357 | 0.57 | 650 |
| 2016 | 1549 | 0.18 | 223 |
| 2017 | 1944 | 0.18 | 443 |

## SUMMARY DISCUSSION

Productivity of Eastern Georges Bank cod has been low for the last two decades, with poor recruitment and truncated age structure. An increase in natural mortality may have contributed to the recent low productivity; however, food habits data do not support this hypothesis (NEFSC 2013b). Analysis of tagging data indicates minimal increase in M from the 1980s to the 2000s, and thus does not appear sufficient to explain the long term low productivity (Miller WP ${ }^{1}$ ). Lack of large numbers of older repeat spawners in the Eastern Georges Bank cod population since the mid-1980s may contribute to the long-term low productivity. Cod have a low success rate of hatching for first and second time spawners (13\% and 62\%) until the third spawning (100\%), suggesting that an expanded age structure of fish that have spawned three or more times would contribute to higher productivity (Trippel 1998; Carr and Kaufman 2009). Long-term overfishing may have also had indirect effects. Fishing activity disrupts the spawning aggregation and thus behaviors and rituals of cod, reducing the potential of good recruitment (Dean 2012). Spawning of cod involves complex behaviors that have only recently been observed, including arrival and departure of fish on the spawning ground at different times dependent upon sex, age, and stage of maturity (Lawson and Rose 2000) and the formation of spawning leks where the males set up and defend territory (Windle and Rose 2007).
The 2015 updated model formulation provides similar results to the 2014 ASAP assessment (Wang et al. 2014), with an increase in the retrospective bias in F and SSB and a decrease in the retrospective bias for recruitment. In the ASAP formulation, additional variability is added to the survey abundance estimates; thus, placing more emphasis on the reported catch data.

Figure B11. ASAP model results of retrospective bias of fishing mortality (F), spawning stock biomass (SSB), and age1 recruitment. Retrospective bias adjustment for $F=-0.36, S S B=0.59$, and age 1 recruitment $=-0.18$.

Figure B12. ASAP model results of trace of MCMC chains for Eastern Georges Bank cod fishing mortality (left) and spawning stock biomass (right) for 1978 and 2013. Each chain had an initial length of 5.0 million and was thinned at a rate of one out of every 2,500th resulting in a final chain length of 2000.
