## Canadà

#### Abstract

The combined 2013 Canada/USA Atlantic cod catches were 463 mt with a quota 600 mt , which was the lowest catch since 1978. Catches from the 2014 DFO and NMFS spring surveys decreased from 2012, and both were among the lowest level in the time series. Both the fishery and the survey catches showed truncated age structure in recent years.

The VPA "M 0.8" model from the 2013 benchmark assessment was used to provide catch advice. In this model, natural mortality ( M ) was assumed to be 0.2 except $\mathrm{M}=0.8$ for ages $6+$ since 1994. A consequence analysis to understand the risks associated with assumptions of the VPA "M 0.8 " and ASAP "M 0.2 " model (with constant M as 0.2 ) was examined in the projection and risk analysis.

While management measures have resulted in a decreased exploitation rate since 1995, total mortality has remained high and adult biomass has fluctuated at a low level. The adult population biomass at the beginning of 2014 was estimated at $11,719 \mathrm{mt}$, which was about $20 \%$ of the adult biomass in 1978. Fishing mortality was high prior to 1994 and was estimated to be 0.04 in 2013, the lowest on record. Recruitment at age 1 has been low in recent years. The 2003 year class was estimated to be the highest recruitment since 2000. The initial estimate of the 2010 year class was stronger than the 2003 year class based on the 2014 assessment. Lower weights at age in the population in recent years and poor recruitment have contributed to the lack of rebuilding.

Considering $\mathrm{F}_{\text {ref }}=0.18$ is not consistent with the assessment VPA "M 0.8 " model, it is inappropriate for the catch advice. TRAC recommends basing catch advice on an $F$ lower than $F_{\text {ref }}$ until a different $F_{\text {ref }}$ is negotiated. An $F=0.11$ was used for the catch advice. A $50 \%$ probability of not exceeding an $F=0.11$ implies catches less than $1,150 \mathrm{mt}$. However, given the extremely low SSB, stock rebuilding should be promoted. Even no fishing in 2015, there would be higher than 50\% risk that 3+ biomass will decrease between 2015 and 2016.

The consequence analysis showed that under both sets of model assumptions, a projected catch of about 600 mt in 2014 would result in low exploitation while achieving a $10 \%$ increase in ages 3+ biomass between 2014 and 2015.

## INTRODUCTION

The basis and background for the delineation of management units of cod on Georges Bank and the vicinity were reviewed and summarized at the 2009 Eastern Georges Bank cod benchmark assessment meeting (O'Brien and Worcester, 2009). For the purpose of a sharing agreement and consistent management by Canada and the USA, agreement was reached that the transboundary management unit for Atlantic cod would be limited to the eastern portion of Georges Bank (DFO Statistical Unit Areas 5Zej and 5Zem; USA Statistical Areas 551, 552, 561 and 562)) (DFO, 2002). The management area is shown in Figure 1. The USA has a requirement for management advice for the Georges Bank cod stock ( $5 Z+$ SubArea 6 ). The status quo has been to use an assessment of cod in 5Zjm for transboundary management advice and an assessment of cod in $5 Z+6$ for USA domestic management advice. While other options could be followed, this option is less disruptive to the existing processes. This approach requires concurrent assessment reviews of $5 Z j m$ and of $5 Z+6$ to harmonize results.
The model formulations established by the 2009 Eastern Georges Bank cod benchmark assessment (Wang et al. 2009) were used for the eastern Georges Bank cod assessment from 2009 to 2012. In recent assessments the results exhibited persistent strong retrospective pattern. The retrospective analysis showed a tendency to overestimate biomass and underestimate fishing mortality in recent years (Wang and O'Brien, 2012). An Eastern Georges Bank cod benchmark assessment was conducted in 2013 to address these concerns and the details of the model formulation that was agreed upon were documented in the proceedings (Claytor and O'Brien, 2013). In the 2013 assessment, the VPA "M 0.8" model from the 2013 benchmark assessment was used to provide catch advice; A consequence analysis to understand the risks associated with assumptions of the VPA "M 0.8 " and ASAP "M 0.2 " model was examined in the projection and risk analysis(Wang and O'Brien, 2013).
The current assessment applied the 2013 benchmark formulations using Canadian and USA fishery information updated to 2013 including commercial landings and discards, the Fisheries and Oceans Canada (DFO) survey updated to 2014, the National Marine Fisheries Services (NMFS) spring survey updated to 2014 and the NMFS fall survey updated to 2013.

## FISHERY

## COMMERCIAL FISHERY CATCHES

Combined Canada/USA catches averaged $17,198 \mathrm{mt}$ between 1978 and 1993, peaked at $26,463 \mathrm{mt}$ in 1982, and then declined to $1,683 \mathrm{mt}$ in 1995 . They fluctuated around $3,000 \mathrm{mt}$ until 2004 and subsequently declined again. Catches in 2013 were 463 mt , including 54 mt of discards (Table 1, Figure 2). Catches include USA and Canadian discards in all years where discard estimates were available.

Canadian catches peaked at $17,898 \mathrm{mt}$ in 1982 and declined to $1,140 \mathrm{mt}$ in 1995 (Table 1, Figure 3). Since 1995, with lower cod quotas, the fishery has reduced targeting for cod through changes in fishing practices, including the introduction of the cod separator panel for bottom trawls in 1999 (Table 2). From 1995-2012, Canadian catches fluctuated between 468 mt and 3,405 mt (Table 1). In 2013, total catch (extracted landings on May. 26, 2013, 395 mt ) including discards were 468 mt against a quota of 513 mt , taken primarily between June and December by otter trawl and longline (Table 3, Figure 4 and 5). All 2013 landings were subject to dockside monitoring and at
sea observers monitored close to \#\#\% by weight of the mobile gear fleet landings, \#\#\% by weight of the fixed gear landings and \#\#\% of the gillnet fleet landings.

Canadian regulations prohibit the discarding of undersized fish from the groundfish fishery. For the Canadian groundfish fishery on eastern Georges Bank during 1978 - 1996, a review was conducted at the 2013 benchmark meeting to evaluate cod discards (unreported catch). Comparison of length frequencies of observer and port samples did not provide evidence of discarding. Since there was little quota regulation of the Canadian Georges Bank cod fishery prior to 1995, landings generally were well below the quota, it was concluded that there was no indication of discarding before 1996 (Claytor and O'Brien, 2013). For the Canadian groundfish fishery from 1997 to 2013, the ratio of sums method, which uses the difference in ratio of cod to haddock from observed and unobserved trips, was applied to estimate discards of cod. (Van Eeckhaute and Gavaris, 2004; Gavaris et al., 2006, 2007a)(Table1). In 2007, no discards were attributed to the mobile gear fleet because of the high observer coverage (99\%) and discards for the fixed gear fleet could not be calculated because of the low observer coverage but were assumed to be negligible as discards had not been detected in previous years (Clark et al., 2008). Cod discards from the 2013 Canadian groundfish fishery were estimated at 21 mt from the mobile gear and fixed gear fishery (Table 1).

Since 1996, the Canadian scallop fishery has not been permitted to land cod. Landings until 1995 included those catches reported by the scallop fishery. The 3-month moving average observed discards rate has been applied to scallop effort to estimate discards from scallop fishery since 2005 (Gavaris et al., 2007b). Estimated discards of cod by the Canadian scallop fishery ranged between 29 mt to 200 mt annually since 1978 (Van Eeckhaute et al., 2005). In 2013, estimated discards of cod by the Canadian scallop fishery were 18 mt (Table 1).

USA catches increased from $5,502 \mathrm{mt}$ in 1978 to $10,550 \mathrm{mt}$ in 1984. With the implementation of the International boundary (the 'Hague Line') between Canada and the United States in 1984 (International Court of Justice 1984), catches declined and subsequently fluctuated around 6,000 mt between 1985 and 1993 (Table 1, Figure 3). Since December 1994, a year-round closure of Area II (Figure 1) has been in effect, with the exception of less than 3 scallop trips per year in 1999-2000, 2004-2006, 2009, and 2011-2013 and a haddock Special Access Program in 2004 (from August 1st to the following January 31st) and since 2010. Minimum mesh size limits were increased in 1994, 1999, 2002 and 2013. Quotas were introduced in May 2004. Limits on sea days, as well as trip limits, have also been implemented (Table 2). With the implementation of a catch share system in 2010, most of the fleets are now managed by quotas. USA catches during $1994-2000$ ranged between 544 mt and $1,204 \mathrm{mt}$ and increased to $1,935 \mathrm{mt}$ in 2003 , then subsequently declined. Total USA catch (landings and discards combined) was 39 mt for calendar year 2013. The majority of USA landings are usually taken by the second calendar quarter with the least amount landed during the third quarter (Figure 5). Otter trawl gear accounted for $92 \%$ and gillnet gear about $8 \%$ of the landings during 2013.
Discards by USA groundfish fleets occur because of trip limits and minimum size restrictions. In September 2008, the 'Ruhle trawl', which reduces by-catch of cod, was authorized for use on eastern Georges Bank. Cod discarded in the eastern Georges Bank area by otter trawl and scallop fisheries were estimated using the NEFSC Observer data from 1989-2013. A ratio of discarded cod to total kept of all species (d:k) was estimated on a trip basis. Total discards (mt) were estimated from the product of d:k and total commercial landings from the Eastern Georges Bank area. In the 2012 SAW55 cod benchmark meeting, 'Delphi' determined mortality rates (otter trawl: 75\%) were applied to the final estimates of USA discards (Table 1). The estimated discards of cod in the groundfish fishery were 15 mt in 2013, a $71 \%$ decrease from 52 mt discarded in 2012 (Table 1, Figure 3).

## SIZE AND AGE COMPOSITION

The size and age compositions of the 2013 Canadian groundfish fishery landings were derived from port and at-sea samples from all principal gears and seasons (Table 4, Figure 6). There were representative samples from the mobile gear and fixed gear fishery over all the fishing months. At-sea samples were pooled with port samples to derive catch at length and age. Landings peaked at $52 \mathrm{~cm}(20 \mathrm{in})$ for bottom trawlers and $67 \mathrm{~cm}(26 \mathrm{in})$ for longliners. Gillnetters caught fewer cod but these fish were larger, peaking at 70 cm ( 28 in ) (Figure 7). The combined landings for all gears peaked at $52 \mathrm{~cm}(20 \mathrm{in})$ (Figure 8). The size composition of cod discards from the 2013 Canadian scallop fishery was derived from at-sea sampling. Cod discards from the scallop fishery peaked at 34 cm (13 in) (Figure 7). The discards from the groundfish fishery were assumed to have the same size composition as the groundfish landings. The Canadian combined cod discards in 2013 from the groundfish and scallop fisheries peaked at 34 to 49 cm (13 to 19 in ) (Figure 8).
The size and age compositions of the 2013 USA fishery landings on eastern Georges Bank were estimated using port samples of length frequencies and age structures collected from all principal gears and seasons by market category (Table 4). The size and age composition of discarded fish were estimated using at-sea observer samples of length frequency and commercial and NEFSC survey age keys from the same area and season. Landings in 2013 peaked at 56 cm ( 22 in ) and discards peaked at 47 cm (19in) (Figure 9).

The total catch composition of combined landings and discards for Canada and the USA is shown in Figure 10. Canadian catches peaked at 52 cm (20 in); and USA catches peaked at 59 cm (22 in).
Canadian catch-at-age composition was obtained by applying quarterly fishery age-length keys to the size composition. The age-length key from the 2013 DFO survey was used to augment the first quarter key.

The age composition of the 2013 USA landings was estimated by market category by applying age-length keys to the size composition pooled by calendar quarter, semi-annually, or annually depending on the number of available length samples. The USA sampling protocol is 1 sample per 100 mt of landings (i.e. where 1 length sample=100 fish and 1 age sample=20-25 fish). The 2013 age-length keys were supplemented with age samples from statistical areas 522 and 525 for the catch at age calculations.

Total discards at age from the USA groundfish and scallop fisheries (1989-2013), the Canadian groundfish fishery (1997-2013) and the Canadian scallop fishery (1978-2013) were all included in the assessment.

The 2013 combined Canada/USA fishery age composition, by number, was dominated by the 2010 year class at age 3 (52\%), followed by the 2009 year class at age 4 (24\%) and the 2011 year class at age 2 (15\%) (Table 5, Figure 11). The 2003 year class at age 9 made little contribution to the 2013 catch ( $0.04 \%$ ). By weight, the 2010 year class dominated the 2013 fishery (44\%) followed by the 2009 (31\%) and 2008 year classes (9\%) (Figure11). The contribution of age 7 and older fish continued to be small in recent years, $1 \%$ by number and $3 \%$ by weight in 2013 (Table 5, Figure 11 and 12).

Fishery weights at age showed a declining trend starting in the early 1990s (Table 6, Figure 15). Compared to 2012, the weights at age in 2013 improved but still at lower levels.

## ABUNDANCE INDICES

## RESEARCH SURVEYS

Surveys of Georges Bank have been conducted by DFO each year (February/March) since 1986 and by NMFS each fall (October) since 1963 and each spring (April) since 1968. All surveys use a stratified random design (Figures 14 and 15). Most of the DFO surveys have been conducted by the CCGS Alfred Needler. A sister ship, the CCGS Wilfred Templeman, conducted the survey in 1993, 2004, 2007 and 2008 and another vessel, the CCGS Teleost, conducted 6 of the sets in 2006. No conversion factors were applied. For the NMFS surveys, two vessels have been employed and there was a change in the trawl door in 1985. Vessel and door type conversion factors derived experimentally from comparative fishing (Table 7) have been applied to the survey results to make the series consistent (Forrester et al. 1997). Additionally, two different trawl nets have been used on the NMFS spring survey, a modified Yankee 41 from 1973-81 and a Yankee 36 in other years, but no net conversion factors were available for cod. A new net and vessel (NOAA ship FSV Henry B. Bigelow), with revised station protocols have been used to conduct the NMFS spring and fall surveys since 2009. Calibration factors by length were calculated for Atlantic cod for the data collected by the Henry B. Bigelow to make the data equivalent to previous surveys conducted by former NOAA ship Albatross IV. The new research vessel/net combination tended to catch more cod at all lengths, but also proportionally more small cod. Length calibration factors (Brooks et al. 2010) were applied to the NMFS spring and fall survey results since 2009 (Table 8).

The spatial distribution of ages 3 and older cod caught during the 2012 NMFS fall, 2013 NMFS spring and 2013 DFO survey were similar to that observed from those surveys over the previous decade, with most fish concentrated on the northeastern part of Georges Bank (Figures 16-18).

The catch in numbers from the 2014 DFO survey was lower than 2012, among the lowest level in the time series (1986-2014) (Table 9). The 2010 year class at age 4 was dominant ( $44 \%$ by number), followed by the 2011 year class at age 3 ( $30 \%$ by number). There was no catch of the 2007 year class at age 7 and no catch of fish older than 8 (Table 9, Figure 19).

Similar to the DFO survey, the 2014 NMFS spring survey catch decreased from 2013 and was among the lowest level in the time series (Table 10). The 2010 year class at age 4 was dominant ( $52 \%$ by number), followed by the 2011 year class at age 3 ( $32 \%$ in number). There were no fish caught older than age 6 (Table 10, Figure 19).

The catch from the NMFS 2013 fall increased from 2012, but was below the average of the time series. The 2010 year class at age 3 and 2011 year class at age 2 were dominant (totally $72 \%$ by number), the 2013 year class accounted for $10 \%$ by number. There were no catches of fish older than age 4 (Table 11, Figure 19).

The coefficient of variation (CV) of stratified mean catch number/tow for the three surveys is shown in Tables 12-14 and Figure 20. Median CV values indicated the most variable catch of ages 1 and 8 for DFO survey, ages 7 and 8 for the NMFS spring survey, as well as ages 1 and 5 for the NMFS fall survey. The CVs were similar between the DFO and NMFS spring surveys and smaller compared to the NMFS fall survey values. The catch from all three surveys became more variable after mid-1990s, which might be caused by patchy distribution at low abundance.
With the exception of the 1996, 1998 and 2003 year classes and potentially the 2010 year class (all of which were below the time series average), the survey abundance at age (Tables 9-11, Figure 19) shows poor recruitment since the 1990 year class in all three surveys. The 2003 year class has appeared strong in the DFO and spring surveys until age 7 and in the fall surveys until age 3 , however they were disappearing very fast after. The 2010 year class was prominent in all
three surveys. Compared with pre-1990 surveys, representation at older ages and younger ages in recent years continues to be poor (Tables 9-11, Figure 19).
For the survey swept area biomass, the 2013 NMFS fall survey biomass increased from the 2012, but still at lower level. In 2014, both the DFO and NMFS spring survey biomass decreased from 2013 and were among the lowest in the time series (Table 15, Figure 21).
The average weights at age derived from the DFO survey and NMFS spring survey were used to represent the population weight at age for the beginning of the year. All the weights at age display a declining trend since the early 1990s (Table 16, Figure 22). Weights at age in 2014 are higher than in 2013 except for ages 2 and 4.
Fulton's condition factor (K), an indicator which uses observed weight and length to measure fish condition, was calculated using the data from all three surveys. In order to reduce the impact of gonad weight, the post-spawning fish samples were used for the Fulton's K calculation. It showed notable downward trends in recent years from DFO and NMFS spring samples. There were limited catches from the NMFS fall survey (Table 11), and the trend from those samples was not clear (Figure 23). All the three surveys show that fish conditions are improved in 2014.

The total mortality ( $Z$ ) was calculated by two age groups (ages 4 and 5 , and ages 6 to 8 ) using DFO and NMFS spring survey abundance indices, separately. It showed that $Z$ of ages 4 and 5 has been lower than the older age group (Figure 24). Z has been high throughout assessment time period for both age groups (Figure 24), although relative F (fishery catch at age/survey abundance indices) declined significantly since mid-1990s (Figure 25).

## HARVEST STRATEGY

The Transboundary Management Guidance Committee (TMGC) has adopted a strategy to maintain a low to neutral risk of exceeding the fishing mortality reference. At the 2013 benchmark meeting, it was agreed that the current $\mathrm{F}_{\mathrm{ref}}=0.18$ (TMGC meeting in December, 2002) is not consistent with the VPA "M 0.8 " model, and a lower value for $\mathrm{F}_{\text {ref }}$ would be more appropriate (Claytor and O'Brien, 2013). When stock conditions are poor, fishing mortality rates should be further reduced to promote rebuilding.

## ESTIMATION AND DIAGNOSTICS

## CALIBRATION OF VIRTURAL POPULATION ANALYSIS (VPA)

At the benchmark assessment review in 2013, there was no consensus on a benchmark model, however, the TRAC did agree to provide catch advice based on a virtual population analysis (VPA) model (Claytor and O'Brien, 2013). The VPA used fishery catch statistics and size and age composition of the catch from 1978 to 2013 (including discards). The adaptive framework, ADAPT (Gavaris 1988), was used for calibrating the VPA with trends in abundance from three research bottom trawl survey series: NMFS spring, NMFS fall and DFO. Computational formulae used in ADAPT are described by Rivard and Gavaris (2003a).
In this model, natural mortality (M) was assumed equal to 0.2 except for ages 6+ from 1994 onwards where M was fixed at 0.8 . The data used in the model were:
$C_{a, t}=$ catch at age for ages $\mathrm{a}=1$ to 10+ and time $t=1978$ to 2013, where $t$ represents the year during which the catch was taken
$l_{1, \mathrm{a}, \mathrm{t}}=$ DFO survey for ages $\mathrm{a}=1$ to 8 and time $t=1986.17,1987.17 \ldots 2013.17,2014.00$
$I_{2, a, t}=$ NMFS spring survey (Yankee 41) for ages $a=1$ to 8 and time $t=1978.28,1979.28$, 1980.28, 1981.28
$I_{3, a, t}=$ NMFS spring survey (Yankee 36), for ages $\mathrm{a}=1$ to 8 and time $t=1982.28,1983.28 \ldots$
2013.28, 2014.00
$I_{4, a, t}=$ NMFS fall survey, ages $a=1$ to 5 and time $t=1978.69,1979.69 \ldots 2012.69,2013.69$
The population was calculated to the beginning of 2014; therefore the DFO and NMFS spring survey indices for 2014 were designated as occurring at the beginning of the year, i.e. 2014.00. The benchmark formulations assumed that observation errors for the catch at age data were negligible. Observation errors for the abundance indices at age were assumed to be independent and identically distributed after taking natural logarithms of the values. Zero observations for abundance indices were treated as missing data as the logarithm of zero is not defined. Fishing mortality on age 9 for 1978 to 2013 was assumed to be equal to the population weighted average fishing mortality on ages 7 and 8.
Estimation was based on minimization of the objective function:
$\sum_{s, a, t}\left(\ln I_{s, a, t}-\left(\hat{\kappa}_{s, a}+v_{a, t}\right)\right)^{2}$, where $s$ indexes survey.
The estimated model parameters were:
$v_{a, t}=\ln N_{\mathrm{a}, \mathrm{t}}=\ln$ population abundance for $\mathrm{a}=2$ to 9 at beginning of 2014
$K_{1, a}=\operatorname{In}$ DFO survey catchability for ages $\mathrm{a}=1$ to 8 at time $\mathrm{t}=1986$ to 2014
$K_{2, a}=\operatorname{In}$ NMFS spring survey (Yankee 41) catchability for ages $a=1$ to 8 at time $t=1978$ to 1981
$K_{3, a}=\ln$ NMFS spring survey (Yankee 36) catchability for ages $a=1$ to 8 at time $t=1982$ to 2014
$K_{4, a}=\ln$ NMFS fall survey catchability for ages $a=1$ to 5 at time $t=1978$ to 2013
Statistical properties of the estimators were determined using conditional non-parametric bootstrapping of model residuals (Efron and Tibshirani 1993, Rivard and Gavaris 2003a).
The population abundance estimate of the 2012 year classes at age 2 at beginning of 2014 exhibited the largest relative bias of $22 \%$ and relative error of $76 \%$. The relative bias for other ages ranged between $3 \%$ and $5 \%$, and the relative error ranged between $40 \%$ and $23 \%$ (Table 17). Survey catchability ( $q$ ) at age progressively increased until age 5 for DFO and NMFS spring surveys (Figure 26). Survey catchability at age for the NMFS fall survey was very low (Figure 26).
The overall fit of model estimated biomass to the DFO, NMFS spring and NMFS fall surveys was generally consistent with the survey trends after 1994 (Figure 27). There were residual patterns which suggested obvious year effects (Figure 28). Average fishing mortality (F4-9) by time blocks for 1978-1993, 1994-2008 and the recent 5 years (2009-2013) was 0.48, 0.27 and 0.09, respectively. The temporal trend of fishing mortality was consistent with fishery management effort trend. There was relatively flat fishery partial recruitment pattern except for the 10+ group (Figure 29).
Retrospective analysis was used to detect any bias of consistently overestimating or underestimating fishing mortality, biomass and recruitment relative to the terminal year estimates. With catch data through 2011, the VPA "M 0.8 " model did not show any retrospective pattern, suggesting that model assumptions on natural mortality are appropriate and that the fishery catch at age is consistent with the survey indices. However, in the assessment with catch data through 2012, the 2003 year class was estimated to be substantially smaller than the estimate from the 2013 benchmark model formulation with one less year of data. It was estimated at 4.1 million at
age 1 in the 2013 compared with 13.5 million with one less year of data (Figures 30 and 31). The estimate was 4.4 million in the 2014 assessment, close to the 2013 assessment. Residuals of the 2003 year class from the three surveys were predominantly positive, which means that the 2003 year class was underestimated in both the 2013 and 2014 assessment (Figure 32). The 2014 assessment results were very close with the 2013 assessment, there was no consistent pattern.

Possible reasons for the appearance of a retrospective bias after adding one more year of data were explored. At the benchmark model review in 2012, with catch data through 2011 as described above, the age 9 in 2012 (2003 year class) was estimated directly as a model parameter. While in the 2013 and 2014 assessment, the determination of the 2003 year class relied on the 2012 fishery age 9 (2003 year class) catch and the assumption that F9 (2003 year class) is equal to the population weighted average F on ages 7 and 8 of adjacent year classes. And there is no age 9 survey abundance indices applied to calibrate the catch-at-age matrix.

The prevalence of age 9 fish in the 2012 fishery catch was expected to be high based on the abundance of the 2003 cohort in each of the previous age classes. However, a proportionately low value of age 9 catch accounted for only $0.3 \%$ in number in the 2012 fishery catch, which led to a much lower estimate of this cohort and contributed to a retrospective bias.

One possible reason for the low value of age 9 (2003 year class) catch in 2012 is if the actual $M$ experienced by the 2003 year class between ages 8 and 9 was higher than that assumed (0.8). Using the assumed M would artificially reduce the abundance of the entire 2003 cohort in the backward calculation (even if the 0.8 is a good approximation of $M$ among ages 6 and 7 ). Sensitivity runs were conducted to explore the uncertainties in estimation of the 2003 year class. The impacts on the estimate of recruitment of other year classes, terminal year (2014) population abundance as well as the implication for the projection were investigated.

## Sensitivity analyses

In the following sensitivity runs, the model set up was the same as the VPA "M 0.8 " model formulation described above for the 2014 assessment except for:

- Run 1: Estimating the 2003 year class at age 9 ('estimate 2003yc' model). In this model, the abundance of the 2003 year class at age 9 in 2012 was estimated as a parameter. Thus, neither age 9 fishery catch nor the assumption on $F$ at age 9 as an average of adjacent year classes was used in the estimation of the age 9 population number of the 2003 year class.
- Run 2: Removing the 2003 year class survey abundance indices entirely from the data input ('without 2003yc' model). In this sensitivity run, the abundance of the 2003 year class at age 9 was arbitrarily fixed at a value of 100 thousands. Since no 2003 year class survey abundance indices were used in the calibration and objective function, this fixed value has no impact on estimation of the other year classes.

The estimated 2003 year class numbers at age from run 1 were compared with the 2012 and 2014 assessments. The 2003 year class at age 1 from the "estimate 2003yc" model was very close to the 2012 assessment at about 13.5 million fish at age 1 , well above 4.1 million from the 2013 and 4.5 million from the 2014 assessment (Table 18, Figure 33). For recruitment in other years, the "estimate 2003yc" model had almost the identical results with the 2012 assessment; while the estimate from the 'without 2003yc' model was closer to the 2014 VPA "M 0.8 " model. The 2014 assessment with "M 0.8" model estimated the 2010 year class at 5.6 million, while about 5.9 and 5.4 million from the 2 sensitivity runs (Table 18, Figure 34). Although the 2014 VPA
"M 0.8 " model tended to underestimate the size of pre-2003 year classes, the estimate for the most recent 3 year classes was very similar among all models (Table 18 and Figure 34).

For the terminal year population abundance estimate, the "estimate 2003yc" model had higher estimate for most age groups compared to the 2014 VPA "M 0.8 " model. There was very minor difference between 'without 2003yc' model and 2014 VPA "M 0.8" model (Table 18 and Figure 35).

For the terminal year biomass, the "estimate 2003 yc " model had the highest estimate of ages 10+ biomass at 915 mt with deeply dome-shaped PR compared with 162 mt from the 2014 VPA "M 0.8" model. However, the difference in the terminal year ages 3-9 biomasses was minor between the VPA "M 0.8" model and 'without 2003yc' model (Table 18 and Figure 36).

The above sensitivity analyses suggested that the low estimate of the 2003 year class may be an outlier which then caused a retrospective bias in the 2013 and 2014 assessment. Removing the 2003 year class abundance indices ("without 2003yc" model) showed that it had little impact on the estimation of other year classes in the terminal year (Table 18, Figure 35 and 36) or recruitments in other years (Table 18, Figure 34) compared with the 2014 assessment using the VPA "M 0.8" model.

## STATE OF RESOURCE

Fixing the retrospective bias could be done by the "est 2003yc" model. However, the adult biomass, recruitment, and fishing mortality estimates were different from the VPA "M 0.8" model (Figure 30). The estimates (Tables 19-21) presented below were from the 2012 benchmark VPA "M 0.8" model.

Adult population biomass (ages 3+) declined substantially from about 52,000 mt in 1990 to below $16,000 \mathrm{mt}$ in 1995, the lowest observed at that time (Table 19, Figure 37). Biomass has subsequently fluctuated between $5,900 \mathrm{mt}$ and $18,800 \mathrm{mt}$. The estimate of $3+$ biomass was $11,179 \mathrm{mt}$ ( $80 \%$ confidence interval: $1,0461 \mathrm{mt}-14,750 \mathrm{mt}$ ) at the beginning of 2014 (Table 19). The increase of $3+$ biomass during 2005-2009 was largely due to the recruitment and growth of the 2003 year class, and since 2011 was largely due to the recruitment and growth of the 2010 year class (Figure 38). High natural mortality, lower weights at age in the population in recent years, and generally poor recruitment have contributed to the lack of sustained rebuilding. Survey biomass indices have been lower since the mid-1990s (Figure 21). The estimated adult population biomass at the beginning of 2014 from the VPA was about one fifth of the 1978 biomass (Figure 37).
Recruitment at age 1 has been low in recent years (Table 20, Figure 37). Since 2000, the 2003 year class at 4.4 million fish at age 1 ( 13.5 million fish at age 1 from the 2012 assessment), had been the highest recruitment estimated. However, the initial estimate of the 2010 year class at 5.4 million age 1 fish is stronger than the 2003 year class based on the 2014 assessment. Both the 2003 and 2010 year classes are around half of the average (about 11 million age 1 fish) during 1978-1990, when the productivity was considered to be higher (Table 21, Figure 37). Recruitment for the 2002 and 2008 year classes are the lowest on record. The current biomass is well below $30,000 \mathrm{mt}$, above which there is expected to be a better chance for higher recruitment (Figure 39).

Fishing mortality (population number weighted average of ages 4-9) was high prior to 1994 (Table 21, Figure 37). F declined in 1995 to $\mathrm{F}=0.11$ due to restrictive management measures and then fluctuated between 0.04 and 0.38 . F in 2013 was estimated to be 0.04 ( $80 \%$ confidence interval: $0.036-0.051$ ). The assessment showed recent reductions in F, and the 2013 fishing mortality was below $\mathrm{F}_{\text {ref }}=0.18$. However, because the current $\mathrm{F}_{\text {ref }}$ was based on an assumption of $\mathrm{M}=0.2$, the value is not appropriate for comparison with the VPA "M 0.8" model results (Claytor and O'Brien 2013).

Yield exceeded surplus production during the early 1990s (Figure 41). Surplus production since the mid-1990s has remained considerably lower than that prior to 1990. Growth of ages 2 to 10 has typically accounted for the greatest percentage of the production (Figure 38). Occasionally, a strong incoming year-class at age 2 makes a greater contribution to production. The 2003 year class made such a contribution in 2005. In 2012 and 2013, yield exceeded surplus production (Figure 41).

## PRODUCTIVITY

Recruitment, age structure, fish growth and spatial distribution typically reflect changes in the productive potential. While management measures have resulted in a decreased exploitation rate since 1995, total mortality has remained high and adult biomass has fluctuated at a low level. The current biomass is well below $30,000 \mathrm{mt}$; when biomass is above this threshold, there is a better chance for higher recruitment (Figure 39). Average weight at length, used to reflect condition, has been stable in the past, but has started to decline in recent years. Size at age in the 2013 fishery remains low (Table 16). The research survey spatial distribution patterns of adult (age 3+) cod have not changed over the past decade (Figures 16-18). Lower weights at age in the population in recent years and poor recruitment have contributed to the lack of rebuilding.

## OUTLOOK

This outlook is provided in terms of consequences with respect to the harvest reference points for alternative catch quotas in 2014 (Gavaris and Sinclair 1998, Rivard and Gavaris 2003b). At the 2013 cod benchmark meeting (Claytor and O'Brien, 2013), it was agreed that the current $\mathrm{F}_{\text {ref }}=0.18$ is not consistent with the VPA "M 0.8 " model given that it was derived based on models with an $\mathrm{M}=0.2$. Although no consensus was reached as to what an appropriate $F_{\text {ref }}$ would be for the VPA "M 0.8 " model, it was agreed that it should be lower. The TRAC agreed that projections would be run at the current $F_{\text {ref }}$ of 0.18 and at a value less than the $F_{\text {ref }}$, and the assessment leads should pick the most meaningful values for the projection. Therefore a value of $\mathrm{F}=0.11$ was used to provide catch advice for 2014. This value was derived from an age-disaggregated SissenwineShepherd production model using $M=0.8$ that was presented at the April 2013 benchmark (Claytor and O'Brien, 2013). Although it was not accepted as $\mathrm{F}_{\text {ref }}$ value for the " M 0.8 " model at the benchmark, the value of $\mathrm{F}=0.11$ was used for the second projection analysis at the 2013 and 2014 TRAC since it was below 0.18 and therefore in keeping with the advice.
Uncertainty about current biomass generates uncertainty in forecast results, which is expressed here as the probability of exceeding $F_{\text {ref }}=0.18$ or $F=0.11$ and as the change in adult biomass from 2015 to 2016. The risk calculations assist in evaluating the consequences of alternative catch quotas by providing a general measure of the uncertainties. However, risk calculations are dependent on the data and model assumptions and do not include uncertainty due to variations in
weight at age, partial recruitment to the fishery, natural mortality, systematic errors in data reporting, the possibility that the model may not reflect stock dynamics closely enough.
For projections, the average of the most recent three years of fishery and survey weights at age is used for fishery and beginning year population biomass for 2015 and 2016. The 2014 and 2015 partial recruitment pattern iss based on the most recent five years of estimated partial recruitment (Table 22). The 2009-2013 geometric mean of recruitment at age 1 is used for 2014-2016 projections, the uncertainties for this estimate is not reflected in the projection. Catch in 2014 is assumed to be equal to the 700 mt quota, and $\mathrm{F}=0.18$ or $\mathrm{F}=0.11$ in 2015.

## Projection based on $\boldsymbol{F}_{\text {ref }}=0.18$

Table 23 shows the deterministic projection results, where the projected catch at $\mathrm{F}_{\text {ref }}=0.18$ would be $1,959 \mathrm{mt}$ in 2015. The stochastic projection indicates a combined Canada/USA catch of 1,850 mt in 2015 will result at neutral risk of F exceeding $\mathrm{F}_{\text {ref }}=0.18$ (Table 24, Figure 42). Because $\mathrm{F}_{\text {ref }}=0.18$ is not consistent with the "M 0.8 " assessment model, it is inappropriate for catch advice.

## Projection based on $F=0.11$

Both deterministic (Table 25) and stochastic (Table 24, Figure 42) projections based on $\mathrm{F}=0.11$ are provided. A $50 \%$ probability of not exceeding $\mathrm{F}=0.11$ implies a combined Canada/USA catch less than $1,150 \mathrm{mt}$ (Table 24, Figure 42). Even no fishing in 2015, there is higher than $50 \%$ risk that 2016 adult biomass will be lower than 2015. Catches of 225 mt will result in a higher risk (75\%) that 2016 adult biomass will not increase (Figure 42).

## Sensitivity analysis

To examine the effect of the uncertainties in the estimation of the 2003 year class, the "estimate $2003 y c$ " model is used as a sensitivity analysis for projections. The strong dome-shaped partial recruitment for ages 10+ from the model results is applied in the projection (Table 22). Deterministic (Table 25) and stochastic (Table 24, Figure 43) projections are provided. A 50\% probability of not exceeding $F_{\text {ref }}=0.18$ implies a combined Canada/USA catch less than $1,900 \mathrm{mt}$, and less than $1,200 \mathrm{mt}$ for $\mathrm{F}=0.11$. Even no fishing in 2015, there is higher than $50 \%$ risk that 2016 adult biomass will be lower than 2015. Catches of 175 mt will result in a higher risk (75\%) that 2016 adult biomass will not increase (Figure 43).

Given the extremely low biomass, management should try to realize the growth potential from the 2010 year class to rebuild the spawning stock biomass. In order to not exceed $\mathrm{F}=0.11$, and to promote stock biomass rebuilding, catches must not exceed 175 mt based on above analysis (Table 24, Figure 42 and 43).

## Consequence Analysis (to be updated)

The risks associated with management actions taken during 2015 are examined with a consequence analysis by undertaking stock projections under the competing assumptions of the 'state of nature'. The two states of nature are the VPA "M 0.8 " model and the ASAP M 0.2 model, both presented at the 2013 cod benchmark model meeting (Claytor and O'Brien 2013) and updated through 2014 in this assessment and will be reviewed at the June 2014 TRAC. At the benchmark model meeting, the TRAC agreed to apply the VPA "M 0.8 " model for providing catch advice, however, given that $\mathrm{F}_{\text {ref }}=0.18$ is no longer consistent with that model, the TRAC also agreed to provide a consequence analysis of projected catch at two different fishing mortality rates from both models.

The analysis presents the consequences of management actions taken by setting projected catch according to the VPA " M 0.8 " model if the true state of nature is such that M has remained unchanged at 0.2 and stock productivity is best reflected by the ASAP M 0.2 model, and conversely, if management actions were taken by setting projected catch according to the ASAP M 0.2 model (Appendix A) while the true state of nature is such that $M$ has increased to 0.8 and stock productivity is best reflected by the VPA "M 0.8 " model.

Data input to each model projection is as previously described for the VPA "M 0.8 " and for ASAP M 0.2 (Appendix A). These are short term projections, for one year to 2015, and do not account for any longer-term consequences.

The column headers in Table 26 represent the 'true' states of nature:

- VPA M $0.8 \mathrm{M}=0.2$ except $\mathrm{M}=0.8$ for ages $6+$ from 1994 onward
- ASAP $0.2 \quad M=0.2$ for all ages and all years

The row headers indicate the basis of the management action during the projected period (2015) for four different catches. The notation in parentheses indicates where that catch was derived, e.g., the row with a $1,225 \mathrm{mt}$ catch was projected from the VPA " M 0.8 " model at $\mathrm{F}=0.11$. The cells of the table indicate the projected 2014 fully recruited $F$ and 2015 January 1 ages 3+ biomass, and the projected percent increase in biomass from 2014 to 2015.

If the VPA "M 0.8 " model assumptions are the 'true state of nature', fishing at projected catch of $2,028 \mathrm{mt}$ at $\mathrm{F}_{\text {ref }}=0.18$ would not allow for a biomass increase in 2015. A 10\% increase in 2015 biomass is only expected fishing at an $\mathrm{F}=0.05$ and a catch of 601 mt . If the ASAP $\mathrm{M}=0.2$ model assumptions are the 'true state of nature', implementing the VPA 0.8 projected catch for $\mathrm{F}_{\text {ref }}$ results in $F=0.75$ and loss of 2015 biomass of about $20 \%$. Fishing at ASAP projected catch of 601 mt at $\mathrm{F}_{\text {ref }}=0.18$ results in projected biomass increase of $10 \%$.

In summary, based on both model projections, 2014 catches at about 600 mt would allow for low exploitation of the stock and at least a minimum $10 \%$ increase in the 2015 projected biomass can likely be attained. A catch of 600 mt would be similar to the recent negotiated quota for fishing years 2012 and 2013.

The consequence analysis reflects the uncertainties in the assessment model assumptions. Despite these uncertainties, all assessment results indicate that low catches are needed to promote rebuilding.

## SPECIAL CONSIDERATIONS

The table 27 summarizes the performance of the management system. It reports the TRAC advice, TMGC quota decision, actual catch, and realized stock conditions for this stock.
Fishing mortality and trajectory of age 3+ biomass from the assessment following the catch year are compared to results from this assessment. These comparisons were kindly provided in 2011 by Tom Nies (staff member of the New England Fishery Management Council (NEFMC)) and updated for this assessment. The inconsistency of TRAC advice in the past with the realized stock conditions from the recent assessment was mainly due to the assessment model changes after the 2009 benchmark assessment, and the retrospective bias in the assessment also accounted for part of this inconsistency.

Cod and haddock are often caught together in groundfish fisheries, although they are not necessarily caught in proportion to their relative abundance because their catchabilities to the fisheries differ. Due to the higher haddock quota, discarding of cod may be high and should be monitored; at-sea observers are an essential component of this monitoring. Modifications to fishing gear and practices, with enhanced monitoring, may mitigate these concerns.

In July 2013, there is a reduction in the minimum size for the US fishery from 22 inches to 19 inches. This is expected to result in reduced discards and a possible change in PR for the youngest ages.

It was agreed at the 2013 TRAC benchmark meeting that projections would be run at the current $F_{\text {ref }}$ of 0.18 and at a value less than 0.18 . A value of $F=0.11$ was used to provide catch advice for 2015. A consequence analysis was used to determine risks under alternative model assumptions. Further investigation will be required to determine an appropriate recommendation for an exploitation rate for the benchmark model.

## ACKNOWLEDGEMENTS

We thank L. Van Eechaute for providing the Canadian discards data, B. Hatt of DFO and N. Shepherd for providing ageing information for the DFO and NMFS surveys and Canadian and USA fisheries., G. Donaldson and D. Frotten of DFO and at sea observers from Javitech Ltd. for providing samples from the Canadian fishery.

Table 2. Canadian (a) and USA (b) fishery management history of cod on eastern Georges Bank, 1978 to 2013.

2a)

| Year | Canadian Management History |
| :---: | :---: |
| 1978 | Foreign fleets were excluded from the 200 mile exclusive economic zones of Canada and USA. |
| 1984 | October implementation of the maritime boundary between the USA and Canada in the Gulf of Maine Area. |
| 1985 | $5 Z$ cod assessment started in Canada; Set TAC; TAC=25,000mt |
| 1986 | TAC=11,000mt |
| 1987 | TAC $=12,500 \mathrm{mt}$ |
| 1988 | TAC $=12,500 \mathrm{mt}$ |
| 1989 | TAC=8,000mt; 5Zjm cod assessment. |
| 1990 | Changes to larger and square mesh size; <br> Changes from TAC to individual and equal boat quotas of 280,000lb with bycatch restrictions; <br> Temporary Vessel Replacement Program was introduced. |
| 1991 | TAC=15,000mt; <br> Dockside monitoring; <br> Maximum individual quota holdings increased to $2 \%$ or 600 t (whichever was less). |
| 1992 | TAC=15,000mt Introduction of ITQs for the OTB fleet. |
| 1993 | TAC=15,000mt, ITQ for the OTB fleet not based on recommended catch quotas; OTB $<65$ fleet was allowed to fish during the spawning season (Mar.-May. 31). |
| 1994 | TAC $=6,000 \mathrm{mt}$, <br> Spawning closures January to May 31; <br> Mesh size was 130 mm square for cod, haddock an Pollock for ITQ fleet; <br> Minimum mesh size of 6 " was required for gillnets; <br> Minimum fish size is 43 cm (small fish protocols) for cod, haddock an Pollock for ITQ fleet; <br> OT> 65' could not begin fishing until July 1; <br> Fixed gear must choose to fish either $5 Z$ or 4 X during June 1 to September 30. |
| 1995 | TAC=1,000mt as a bycatch fishery; <br> January 1 to June 18 was closed to all groundfish fishery; <br> 130 mm square mesh size for all mobile fleets; <br> Small fish protocols continued; <br> $100 \%$ dock side monitoring; <br> Fixed gear vessels with a history since 1990 of 25 mt or more for 3 years of cod, Haddock, Pollock, hake or Cusk combined can participate in $5 Z$ fishery. |
| 1996 | TAC=2,000mt; <br> Prohibition of the landing of groundfish (except monkfish) by the scallop fishery; <br> ITQ vessel require minimum 130 mm square mesh for directed cod, Haddock and Pollock trips; <br> Small fish protocols continued; <br> For community management, quota allocation of each fixed gear based on catch history using the years 1986-1993; <br> $100 \%$ mandatory dockside monitoring and weighout. |
| 1997 | TAC $=3,000 \mathrm{mt}$ |
| 1998 | TAC $=1,900 \mathrm{mt}$ |
| 1999 | TAC=1,800mt; <br> Mandatory cod separator panel when no observer on board; Jan. and Feb. mobile gear winter Pollock fishery. |
| 2000 | TAC=1,600mt; <br> Jan. and Feb. mobile gear winter Pollock fishery. |
| 2001 | TAC=2,100mt |
| 2002 | TAC=1,192mt |

| 2003 | TAC=1,301mt |
| :---: | :--- |
| 2004 | TAC=1,000mt; <br> Canada-USA resource sharing agreement on Georges Bank. |
| 2005 | TAC=740mt; <br> Exploratory winter fishery Jan. to Feb. 18, 2005; <br> Spawning protocol: 25\% of maturity stages at 5 and 6. |
| 2006 | TAC=1,326mt; <br> Exploratory winter fishery Jan. to Feb.6, 2006; <br> Spawning protocol: 30\% of maturity stages at 5 to 7. |
| 2007 | TAC=1,406mt; <br> Exploratory winter fishery Jan. to Feb. 15, 2007; <br> High mobile gear observer coverage (99\%); <br> Spawning protocol: 30\% of maturity stages at 5 to 7. |
| 2008 | TAC=1,633mt; <br> Winter fishery from Jan.1 to Feb. 8, 2009; <br> At sea observer coverage 38\% by weight of the mobile gear fleet landings and $21 \%$ by weight of the fixed <br> gear landings; <br> Spawning protocol: 30\% of maturity stages at 5 to 7. |
| 2009 | TAC=1,173mt; <br> Winter fishery from Jan. 1 to Feb. 21, 2009; <br> At sea observer coverage 23\% by weight of the mobile gear fleet landings and $15 \%$ by weight of the fixed <br> gear landings; <br> Spawning protocol: 30\% of maturity stages at 5 to 7. |
| 2010 | TAC=1,350mt; <br> Winter fishery from Jan. 1 to Feb. 8, 2010; <br> At sea observer coverage 18\% by weight of the mobile gear fleet landings and $6 \%$ by weight of the fixed gear <br> landings; <br> Spawning protocol: 30\% of maturity stages at 5 to 7. |
| 2012 | TAC=1,050mt; <br> Winter fishery from Jan. 1 to Feb. 5, 2011; <br> At sea observer coverage 19\% by weight of the mobile gear fleet landings, 20\% by weight of the fixed gear <br> landings and 3\% by weight of the gillnet fleet landings; <br> Spawning protocol: 30\% of maturity stages at 5 to 7. |
| TAC=513mt; <br> Winter fishery from Jan. 1 to Feb. 6, 2012; <br> At sea observer coverage 42\% by weight of the mobile gear fleet landings, 26 \% by weight of the fixed gear <br> landings and 35\% by weight of the gillnet fleet landings; <br> Spawning protocol: 30\% of maturity stages at 5 to 7. |  |
| TAC=504mt; <br> Winter fishery from Jan. 1 to Feb. 3, 2013; <br> At sea observer coverage \#\#\% by weight of the mobile gear fleet landings, \#\#\%by weight of the fixed gear <br> landings and 35\% by weight of the gillnet fleet landings; <br> Spawning protocol: 30\% of maturity stages at 5 to 7. |  |
| 2013 |  |

| Year | Regulatory Actions |
| :---: | :---: |
| 1953 | ICNAF era |
| 1973-1986 | TAC implemented for Div 5Zcod; 35,000/year |
| 1977 | Groundfish Fishery Management Plan (FMP) Magnuson-Stevesn Conservation Management Act (MSCMA) |
| 1982 | Interim FMP |
| 1984 | Hague Line implemented |
| 1985 | Multi-species FMP |
| 1989 | Amendment 2 |
| 1994 | Emergency Rule - December Year round closures in effect |
| 1994 | Amendment 5; Days at Sea (DAS) monitoring ; Mandatory reporting : Vessel Trip Reports (VTR) |
|  | Amendment 6 |
| 1996 | Amendment 7; accelerated DAS reduction |
|  | Sustainable Fisheries Act (SFA) |
| 1999 | Amendment 9 |
| 2002 | Interim rule ; 20 \% reduction in DAS |
| 2004 | Amendment 13; further reduction in DAS; hard TAC on EGB haddock and cod |
|  | Eastern US/CA Area haddock Special Access Program (SAP) Pilot Progam |
| 2005 | DAS vessels limited to one trip/month in Eastern US/CA Area until April 30; |
|  | Limited accesss DAS vessels required to use separator panel trawl in the area |
| 2006 | Haddock separator trawl or flounder net required in Eastern US/CA area |
| 2008 | Eastern US/CA Area access delayed until Aug 1, except longline gear |
|  | Sept - Ruhle trawl (eliminator trawl) allowed in Eastern US/CA area |
| 2009 | Nov- Eastern US/CA area, trawl vessels requried to use separator/Ruhle south 41-40N |
| 2010 | Amendment 16, Framwork 44 implemented; Sector management ; Prohibition on discarding legal size fish |
|  | US/CA area:prohibition on discarding legal size fish |
|  | Mesh Sizes (inches) |
| 1953 | 4.5 |
| 1977 | 5.125 |
| 1983 | 5.5 |
| 1987 | 6.0 |
| 1989 | eliminate 6 inch increase |
| 1994 | 6.0 |
| 1999 | 6.5 square mesh/ 6.0 diamond mesh |
| 2000 | 6.5 square mesh/ 6.5 diamond mesh |
| 2002 | 6.5 square mesh/ 6.5 diamond mesh/6.5 gill net |
|  | Minimum Size |
| 1977 | 16 inches( 40.6 cm ) commercial and recreational |
| 1982 | 17 inches ( 43.2 cm ) commercial; 15 inches ( 38.1 cm ) recreational |
| 1986 | 19 inches ( 48.3 cm ) commercial; 17 inches ( 43.2 cm ) recreational |
| 1988 | 19 inches ( 48.3 cm ) commecial and recreational |
| 1997 | 21 inches (53.3) recreational |
| 2002 | 22 inches ( 55.9 cm ) commercial; 23 inches ( 58.4 cm ) recreational |
| 2003 | 21 inches ( 53.3 cm ) recreational |
| 2013 | 19 inches ( 48.3 cm ) commercial |

Table 2b. cont.

| Year | Trip Limits |
| :---: | :---: |
| 2004 | GB cod: 1,000 lbs/day; 10,000 lbs/trip; EGB: hard TAC on cod $500 \mathrm{lbs} / \mathrm{day}$; 5,000 lbs/trip in Eastern US/CA area |
| 2005 | $500 \mathrm{lbs} / \mathrm{day}$; 5,000 lbs/trip in Eastern US/CA area |
|  | Starting July, one trip/month in Eastern US/CA area until Apr. 30, 2006 |
| 2006 | $500 \mathrm{lbs} / \mathrm{day}$; 5,000 lbs/trip in Eastern US/CA area |
| 2007 | $1000 \mathrm{lbs} /$ trip of cod in Eastern US/ CA area or Haddock SAP |
| 2008 | $1000 \mathrm{lbs} /$ trip of cod in Eastern US/ CA area fishing EGB exlclusively |
| 2009 | Mar-500 lbs/ trip of cod in Eastern US/CA area; back to 1000 in April |
|  | Apr 16 - Eastern US/CA area closed until May 1 |
| 2010 | GB Cod: $2000 \mathrm{lbs} /$ day; 20000/trip ; EGB cod: $500 \mathrm{lbs} /$ day, $5000 \mathrm{lbs} / \mathrm{trip}$ |
| 2011 | March- 3,000 lbs day during April |
|  | $500 \mathrm{lbs} /$ day after April in EGB area |
|  | Closures |
| 1970 | Area 1(A) and 2 (B) Mar-Apr |
| 1972-1974 | Area 1(A) and 2 (B) Mar-May |
| 1977 | seasonal spawning closure |
| 1987 | modify closed area I to overlap with haddock spawning area |
| 1994 | Jan. CA Il expanded, closed Jan-May, CA I closed to all vessels except sink gillnet |
|  | Dec. CA I and II closed year round to all vessels |
| 1999 | scallopers allowed limited access to CA II |
| 2004 | May to Dec. access to northern corner of CLII \& adjacent area to target haddock w/ separator trawl |
| 2005 | Jan - Eastern US/CA area reopened |
|  | Apr-Eastern US/CA area closed until April 30 |
|  | Aug -Eastern US/CA area closed )GB cod TAC projected near 90\%) |
| 2006 | Eastern US/CA haddock SAP delayed opening until Aug. 1 |
| 2007 | april 25 - Eastern US/CA area closed until Apr. 30 |
|  | Jun - Eastern US/CA area closed to limited access multispecies TAC (due to cod catch) |
|  | Oct- Eastern US/CA area open to limited access multispecies TAC |
|  | Nov- Eastern US/CA area closes |
| 2008 | May- Eastern US/CA area delayed opening until Aug. 1; |
|  | Jun- Eastern US/CA area delayed opening until Aug. 1 for all gear (prevent catching 1st qtr cod TAC) |
| 2009 | May-Eastern US/CA area closed until Aug. 1 for trawl vessels |
| 2010 | Apr-Eastern US/CA area closed ; May 1 opening delayed until August |

Table 10. Indices of swept area abundance (thousands) for eastern Georges Bank cod from the NMFS spring survey. Conversion factors to account for vessel and trawl door changes have been applied. During 1973-1981 a Yankee 41 net was used rather than the standard Yankee 36 net.

Table 15. Swept area biomass (mt) for eastern Georges Bank cod from the DFO, NMFS spring and fall surveys. Conversion factors to account for vessel and trawl door changes have been applied, the biomass conversion factor used for the Henry B . Bigelow since 2009 is 1.58 , the numbers in brackets show the unconverted values.

| Year | NMFS Fall |  | NMFS spring |  | DFO |

Figure 1. Fisheries statistical unit areas (CANADA and USA) in NAFO Subdivision 5Ze. The eastern Georges Bank management unit is outlined by a heavy black line.

Figure 2. Catches of cod from eastern Georges Bank, 1978 to 2013.

Figure 3. Canadian and USA landings and discards of cod from eastern Georges Bank, 1978 to 2013.

Figure 4. Proportion of Canadian gear specific landings of cod from eastern Georges Bank for 1978 to 2012.

Figure 5. Proportion of Canadian and USA quarterly landings of cod from eastern Georges Bank, 1978 to 2012.

Figure 6. Landings (wide bars) and sampling (narrow dark bars) of cod by gear and month from the 2013 Canadian bottom trawl (OTB), longline (LL) and gillnet (GN) fisheries on eastern Georges Bank.

Figure 7. Cod catches at length by gear from the 2013 Canadian fisheries on eastern Georges Bank.

Figure 8. Cod landings and discards at length from the 2013 Canadian fisheries on eastern Georges Bank.

Figure 9. Cod landings and discards at length from the 2013 USA fisheries on eastern Georges Bank.

Figure 10. Cod length frequency from the 2013 Canadian and USA fisheries on Eastern Georges Bank.

Figure 11. Catch at age in numbers (left) and weight (right) for landings and discards of cod from the 2013 eastern Georges Bank fisheries.

Figure 12. Total catch at age (numbers) of cod (left) and proportion of catch at age from eastern Georges Bank for 1978 to 2013. The bubble area is proportional to the magnitude. The light green circles are the 2003 year class and the light blue circles are the 2010 year class.

Figure 13. Average weight at age for ages 2 to 9 of cod from the eastern Georges Bank fishery, 1978 to 2013.

Figure 14. Stratification used for the NMFS surveys. The eastern Georges Bank management unit is indicated by shading.

Figure 15. Stratification used for the DFO survey. The eastern Georges Bank management unit is indicated by shading.

Figure 16. Spatial distribution of age 3+ cod on eastern Georges Bank from the DFO survey for 2014 (right panel) compared to the average for 2004 to 2013 (left panel).

Figure 17. Spatial distribution of age 3+ cod on eastern Georges Bank from the NMFS spring survey for 2014 (right panel) compared to the average for 2004-2013(left panel).

Figure 18. Spatial distribution of age 3+ cod on eastern Georges Bank from the NMFS fall survey for 2013 (right panel) compared to the average for 2003-2012 (left panel).

Figure 19. Survey abundance at age (numbers) of eastern Georges Bank cod. The bubble area is proportional to magnitude within each survey. Conversion factors to account for changes in door type, net and survey vessel were applied to the NMFS surveys. The NMFS spring survey was conducted using a modified Yankee 41 during 1978 to 1981 (lighter bubbles). The 2003 year class is identified with green bubbles and the fuschia bubbles show the 2010 year class.

Figure 20. Stratified mean number/tow and coefficient of variation (CV) for DFO, NMFS spring and fall survey catch of EGB cod.

Figure 21. Survey biomass indices (ages 1+) for eastern Georges Bank cod from the DFO spring and NMFS spring and fall surveys, 1978 -2014.

Figure 22. Beginning of year weight at age of eastern Georges Bank cod from DFO and NMFS spring surveys. The lines show the smoothed values using the LOESS method.

Figure 23. Fish condition (Fulton's K) for eastern Georges Bank cod.

Figure 24. Total mortality(Z) calculated using the DFO and NMFS spring surveys data for eastern Georges Bank cod.

Figure 25. Relative F for eastern Georges Bank cod.

Figure 26. Survey catchability $(q)$ for the DFO, NMFS spring and NMFS fall surveys for eastern Georges Bank cod.

Figure 27. Age 1+ biomass from survey and VPA estimation.

Figure 28. Residuals by year and age group from survey indices for eastern Georges Bank cod. Solid bubbles indicate positive values, open bubbles indicate negative values and the bubble area is proportional to magnitude. The NMFS spring survey was conducted using a modified Yankee 41 from 1978 to 1981 (pale blue bubbles).

Figure 29. Average fishing mortality ( $F$ ) for eastern Georges Bank cod in three time series blocks (1978-1993, 1994-2007, 2008-2012).

Figure 30. Retrospective patterns for recruitment at age 1, 3+ biomass and fishing mortality of eastern Georges Bank cod for the " M 0.8 " model in 2013 assessment. 'estimate 2003yc' is the sensitivity run in 2014.

Figure 31. Relative retrospective patterns for recruitment at age 1, 3+ biomass and fishing mortality of eastern Georges Bank cod for the "M 0.8" model in 2014 assessment.

Figure 32. Residuals of the predicted survey values of the 2003 year class for the " M 0.8 " model in 2013 and 2014 assessment.

Figure 33. The estimated population abundance at age of the 2003 year class from different model formulations of eastern Georges Bank cod.

Figure 34. The estimated recruitment from different model formulations of eastern Georges Bank cod.

Figure 35. The estimated beginning of year 2014 population abundance at age from different model formulations of eastern Georges Bank cod.

Figure 36. The estimated beginning of year 2014 ages 3-9 population biomassfrom different model formulations of eastern Georges Bank cod.

Figure 37. Adult biomass (ages $3+$ ) and year class abundance at age 1 for eastern Georges Bank cod.

Figure 38. Components of annual production for eastern Georges Bank cod attributable to growth of ages 2 to 10 and to the amount contributed by incoming year classes at age 2.

Figure 39.. Relationship between adult biomass (ages 3+) and recruits at age 1 for eastern Georges Bank cod. The red arrow indicate the 2010 year class at age 1.

Figure 40. Average fishing mortality rate at ages 4 to 9 and catches for eastern Georges Bank cod. The established fishing mortality threshold reference, $\mathrm{F}_{\text {ref }}=0.18$.

Figure 41. Surplus production of eastern Georges Bank cod compared to harvested yield.

Figure 42. Risk of 2015 fishing mortality exceeding proposed $F_{\text {ref }}=0.11$ and 2016 biomass not increasing, and 2016 biomass not increasing by $10 \%$ from 2015 for alternative total yields of eastern Georges Bank cod from the "M 0.8 " model formulation.

Figure 43. Risk of 2015 fishing mortality exceeding proposed $F_{\text {ref }}=0.11$ and 2016 biomass not increasing, and 2016biomass not increasing by $10 \%$ from 2015 for alternative total yields of eastern Georges Bank cod from the "estimate 2003yc" formulation.
