# Development of a Sharing Allocation Proposal for Transboundary Resources of 

Cod, Haddock and Yellowtail Flounder on Georges Bank

Prepared by:
The Transboundary Management Guidance Committee

January 2002

#### Abstract

The USA and Canada have embarked on renewed discussions to develop consistent management for the transboundary resources of cod, haddock and yellowtail on Georges Bank. With the declaration of exclusive economic zones by the USA and Canada in 1977, both nations claimed a disputed zone on eastern Georges Bank. A bilateral agreement negotiated in 1979 was never ratified. The dispute was referred to the International Court of Justice and in October 1984, the Court delivered its judgement establishing the international maritime boundary.

While fishing activities by the USA and Canada were subsequently restricted to their respective territories, the border did not resolve all fisheries management concerns. Fishing intensity for groundfish increased rapidly during the late 1980s on both sides of the border. Coordination of fisheries management strategies was virtually non existent in those early years after the establishment of the border. Calls to reduce exploitation were countered by arguments that conservation efforts were futile because the fish would be caught on the other side of the boundary anyway.

The 1992 year-class of haddock appeared promising and informal discussions between authorities led to a commitment by both the USA and Canada to limit harvesting and to use this potential towards rebuilding. The success of these coordinated actions promoted increased discussion of common concerns regarding transboundary resources. In 1998, the Transboundary Resource Assessment Committee (TRAC) was formed to realize efficiencies in conducting stock evaluations of transboundary resources and to ensure the advice was based on the best available combined information. Consultations on fisheries management matters culminated in the formation of the Transboundary Management Guidance Committee (TMGC) in 2000.

The terms of reference for the TMGC included providing guidance on principles and options for determining a resource sharing strategy. In December 2001, the TMGC reached an agreed proposal that they could recommend to administrators. They agreed to use 5 Zjm as the management unit for cod and haddock and 5Zhjmn for yellowtail, with percentage share based on contemporary resource distribution and on landings during 1967-1994. The sharing formula gives weighting of $60 \%$ to resource distribution and $40 \%$ to landings in 2003, the initial year. The weighting of resource distribution would progressively increase reaching $90 \%$ ( $10 \%$ for landings) by 2010, the end of the transition period.

## RÉSUMÉ

Les États-Unis et le Canada ont entrepris à nouveau des discussions en vue de mettre en place une gestion harmonieuse des stocks transfrontaliers de morue, d'aiglefin et de limande à queue jaune sur le banc Georges. Lorsqu'elles ont institué leurs zones économiques exclusives, en 1977, les deux nations ont revendiqué chacune une certaine partie de l'est du banc Georges. L'entente bilatérale qui avait été négociée à ce sujet en 1979 n'a jamais été ratifiée. Le litige a donc été porté devant la Cour internationale de justice, qui, en octobre 1984, a rendu son jugement établissant la frontière maritime internationale.

Quoique les activités de pêche des États-Unis et du Canada aient été par la suite limitées aux territoires respectifs des deux pays, l'établissement de la frontière n'a pas réglé tous les problèmes de gestion des ressources visées. L'effort de pêche du poisson de fond s'intensifia rapidement à la fin des années 1980, de part et d'autre de la frontière. Il faut dire que dans les premières années qui suivirent la création de la frontière, la coordination des stratégies de gestion des pêches était pratiquement inexistante. Aux appels lancés en vue de réduire l'exploitation on rétorquait que les tentatives de conservation étaient vaines car, de toute façon, le poisson serait capturé de l'autre côté de la frontière.

Parmi le stock d'aiglefin, la classe d'âge de 1992 semblait prometteuse; aux termes de discussions entre leurs autorités respectives, les États-Unis et le Canada s'engagèrent tous deux à limiter la pêche et à tirer parti du potentiel que représentait cette classe d'âge pour rétablir le stock. Le succès de ces mesures coordonnées eut pour effet d'encourager la discussion sur les préoccupations communes concernant les ressources transfrontalières. En 1998, on mit sur pied le Comité d'évaluation des ressources transfrontalières (CERT), qui avait pour but de rationaliser les évaluations de stocks transfrontaliers et de faire en sorte que les avis scientifiques concernant ces stocks soient fondés sur les meilleurs renseignements dont disposaient les deux pays. Les consultations sur la gestion des pêches aboutirent à la création du Comité d'orientation de la gestion des stocks transfrontaliers (COGST), en 2000.

Le COGST est chargé notamment de donner des conseils sur les principes et les options à prendre en considération pour établir une stratégie de partage des ressources halieutiques. En décembre 2001, le COGST s'entendit sur une proposition à recommander aux administrateurs. Il s'agissait d'utiliser les divisions 5 Zjm comme unité de gestion de la morue et de l'aiglefin et les divisions 5Zhjmn comme unité de gestion de la limande à queue jaune, et de fonder les parts respectives sur la distribution actuelle des ressources et sur les débarquements de 1967 à 1994. La formule de partage accorde une pondération de $60 \%$ à la distribution des ressources et de 40 $\%$ aux débarquements en 2003, première année de son application. Il est prévu que la pondération de la distribution de la ressource augmente progressivement jusqu'à $90 \%$ ( $10 \%$ pour les débarquements) d'ici 2010, année marquant la fin de la période de transition.

## BACKGROUND

Since 1977, with the declaration of exclusive economic zones by coastal states, only the USA and Canada have conducted fisheries for groundfish on Georges Bank. Immediately prior to this, the fisheries on Georges Bank fell under the mandate of the International Commission for the Northwest Atlantic Fisheries. The Commission coordinated stock evaluations and was also involved with management. Distant water fleets from various nations expanded their fishing intensity on Georges Bank during the 1960s. The Commission was concerned with moderating this fishing effort and introduced catch quotas and area/season closures in the early 1970s.

After 1977, the USA and Canada used national institutions for stock evaluation. The analyses were supported by exchanges of respective fishery and scientific information as well as complementary participation in the review processes. The USA developed a Multispecies Fisheries Management Plan and turned largely to input controls, i.e. area/season closures, mesh size, trip limits, etc., for regulation, with all catch quotas being eliminated by the early 1980s. In addition, beginning in 1994 the USA implemented effort control mechanisms to reduce fishing pressure on groundfish stocks. The key components of the effort control measures included a limited entry program and a days-at-sea (DAS) program, which reduced the amount of time a vessel owner can participate in the groundfish fishery. By contrast, Canada embraced output controls, principally catch quotas, for regulation and developed reporting and monitoring systems to support it. Though both the USA and Canadian management systems have evolved over the years, this distinction remains (see Attachment 1 for details).

The declaration of exclusive economic zones by the USA and Canada in 1977 gave rise to conflicting interest, with both nations claiming a disputed zone on eastern Georges Bank. Negotiations resulted in the proposed East Coast Fisheries Bilateral Agreement in 1979. Dissatisfaction with the terms of the agreement led to intense lobbying by fishing interests, and while both sides had signed the agreement, it was never ratified. The USA and Canada agreed to refer the boundary dispute to the International Court of Justice. In October 1984, the Court delivered its judgement and the international maritime boundary between the USA and Canada was established.

While fishing activities by the USA and Canada were subsequently restricted to their respective territories, the boundary did not resolve all fisheries management concerns. Several fisheries resources on Georges Bank are considered transboundary. A transboundary resource is one whose distribution spans the boundary and for which there is substantial migration and movement across the boundary. Active fisheries by the USA and Canada on Georges Bank for cod and haddock gave these transboundary resources a higher profile. Fishing intensity for groundfish increased rapidly during the late 1980s on both sides of the boundary. Calls to reduce exploitation were countered by arguments that conservation efforts were futile because the fish would be caught on the other side of the boundary anyway. While coordination of fisheries management strategies was virtually non-existent in those early years after the establishment of the boundary, USA and Canada reached agreement to cooperate in enforcing illegal incursions across the boundary.

Recognizing the spatial complexity of the cod and haddock resources on Georges Bank, Canada adopted eastern Georges Bank (unit areas 5 Zj and 5 Zm or 523 and 524, see map in Attachment
2) as the management unit in the early 1990s. While full benefits from the fisheries in this management unit would require consistent management with the USA, it was expected that independent action could contribute to rebuilding and sustainability. Consequently, Canada introduced restrictive catch quotas aimed at recovery of these resources, and in particular, haddock. At about the same time, there were increasing concerns in the USA about the state of the haddock resource and this led to spatial and temporal extensions of the area/season closures in 1994. The 1992 year-class of haddock appeared promising and informal discussions between authorities led to a commitment by both the USA and Canada to limit harvesting and to use this potential towards rebuilding.

## TRAC PROCESS

The success of these coordinated actions promoted an increased frequency of informal meetings between USA and Canadian authorities to discuss common concerns regarding transboundary resources. In 1998, the Transboundary Resource Assessment Committee was formed to realize efficiencies in conducting stock evaluations of transboundary resources and to ensure the advice was based on the best available combined information (see Attachment 3). The successful implementation of a joint review process served to emphasize the differences in fisheries management responses to the common perception of stock status. This stimulated concerted discussions regarding how to bring about consistent management for cod, haddock and yellowtail.

Early meetings were aimed at enhancing understanding of the respective fisheries management systems and processes (see Attachment 4). An initial concern was the divergent use of stock status evaluations and the timeliness of the provision of advice. For the USA, fishery management plans in any given year were based on stock status evaluations of the previous year, while for Canada, they were based on the stock status evaluation of the same year. This difference reflected differences in fishing years and in the duration of the public consultation process. A Timing Working Group was tasked with identifying the timeline options, beginning with the TRAC review process and ending with plan approval, which:

- make best use of available data;
- minimize differences in information used to draft plans by USA and Canada;
- consider operational concerns of industry;
- consider administrative constraints; and
- consider workload constraints.

The meeting was held in Portland, Maine on 16 December 1999 and several options were identified. Subsequent clarification of the mandate and further consultations resulted in refinement of the options. Full resolution of a preferred option was deferred until other aspects of consistent management were dealt with.

## FORMATION OF TRANSBOUNDARY MANAGEMENT GUIDANCE COMMITTEE (TMGC)

Another concern was development of a management advisory process. The Working Group on Consistent Management of Transboundary Resources was tasked with recommending the institutional structures required for accomplishing this. These consultations culminated in the formation of the Transboundary Management Guidance Committee (TMGC) consisting of 6 members (two government and four industry) from each of Canada and the USA, to be cochaired by members from each side and to provide non-binding guidance to the two parties. The final agreed Terms of Reference were:

1. Develop process for implementation of TMGC's recommendations.
2. Recommend F-based harvesting strategies that are consistent with USA and Canadian objectives.
3. Provide guidance on principles and options for determining a USA/Canadian resource sharing strategy.
4. Make recommendations for actual US and Canadian harvest levels.
5. Make other recommendations that are mutually beneficial to USA and Canadian fisheries.

In addition, it was also agreed to establish a common database for transboundary resources in the Gulf of Maine, covering as long a time period and as fine a spatial scale as reasonable, including:
(a) historical catch data;
(b) research vessel survey data; and
(c) biological information on migration patterns, spawning areas and nursery grounds.

## SHARING PROPOSALS

A Technical Working Group of the TMGC was tasked with developing a pilot common database, with priority on cod, haddock and yellowtail. At the 14-15 May 2001 meeting of the TMGC, recommendations for refining the database were made, it was agreed that there was scope to develop a common USA/Canada F based harvest strategy and there were preliminary discussions on principles for sharing arrangements. Senior administrators then tasked the TMGC to complete the refinements to the database, simultaneously exchange proposals for sharing allocations and to follow with a meeting to discuss the proposals. Both the pilot database for cod, haddock and yellowtail (see Attachment 5) and initial sharing proposals (see Attachments 6 and 7) were completed in 2001.

At its 5-6 September 2001 meeting in Portland, Maine, the USA and Canada discussed each proposal. The key objective of the Canadian proposal involved a consistent management strategy with a uniform exploitation rate across the respective areas. Two key elements to determine resource shares were resource utilization and distribution. Canada identified the implementation of the ICJ boundary as an integral part of its proposal and noted that any utilization prior to 1985 was not considered. Utilization from 1985-2000 was only considered with weighting of 5\% while resource distribution was $95 \%$. The proposal considers either a combined stock complex
of 5 Z with the caveat of additional management measures, or the smaller stock component of 5 Zjm for cod and haddock.

The USA proposal was based on the following four elements: 1) Time period: Selected based on anticipated stock distribution for rebuilt stocks. Stocks have wider distribution when near MSY;
2) Management unit: Considered the bank as a single management unit, resulting in a whole bank distribution and management unit scheme; 3) Weighting: Landings and surveys are considered equally important as proxies for resource distribution and historic dependence; and 4) Research investment element: Consider historic research investments, as recognized in international agreements. Offers very simple proxy using relative number of groundfish surveys.

Given the wide disparity in the resource distribution implied in both proposals, a sharing agreement based on distribution that was more sensitive to the rate of change was preferred to the two extreme proposals offered. The USA and Canada developed constructive suggestions to bridge the differences. The suggestions included:

- agreement on a technique to establish current trends in resource distribution (Attachment 8);
- combining and normalizing the results for resource utilization from the proposed USA time period and the proposed Canadian time period; and
- transition from roughly equal importance to resource utilization and resource distribution to greater importance given to resource distribution.

## SHARING AGREEMENT

The 3-5 December meeting of TMGC in Halifax, Nova Scotia, explored these avenues and finally arrived upon an agreed proposal that they could recommend to administrators (see Attachment 9). As with any negotiated settlement, the agreed proposal is a compromise. The USA and Canada reached consensus to use 5 Zjm as the management unit for cod and haddock, apply a responsive smoothing procedure, employ the average of three surveys for yellowtail flounder and haddock and the average of two seasons for cod, base landings on the 1967-1994 time period and incorporate a fixed 7-year transition schedule. As an additional consideration, as part of the sharing agreement, the USA and Canada reconfirmed that the two countries develop a common fishing mortality based harvest strategy for the shared management units.

The underlying motivation that fuelled the effort to reach an agreement was the recognition that each countries independent conservation actions could be compromised and that the full benefits of management actions were more likely to be realized if there was consistent management by the USA and Canada. Cod and haddock resources reached historic low abundance in the early to mid 1990s as a consequence of high fishing intensity from both Canada and USA when coordination of management was at its lowest ebb. Partly due to concerted actions by the USA and Canada during the 1990s, haddock has shown strong rebuilding. Cod has increased in abundance somewhat, but remains a concern (see Attachment 10). Continued efforts to pursue consistent management by the USA and Canada are needed. The proposal for a sharing allocation is a first step. The TMGC has been tasked with turning its attention to the remaining Terms of Reference.

Attachment 1. USA and Canadian Management Measures
The USA fishery is almost exclusively conducted by larger mobile gear vessel in the 75 ' range using bottom otter trawl gear. Management has relied primarily on input controls such as area/season closures and mesh size regulation. All catch quota controls were eliminated in 1982 when the minimum landing size regulations were introduced. Further gear regulations were subsequently introduced in 1985. In 1994 the USA implemented effort control mechanisms to reduce fishing pressure on groundfish stocks. The key components of the effort control measures included a limited entry program and a days-at-sea (DAS) program, which reduced the amount of time a vessel owner can participate in the groundfish fishery. Additional measures such as additional DAS reductions, trip limits, and increased minimum mesh sizes have also been used.

The Canadian fishery is conducted primarily by inshore vessels less than $65^{\prime}$ with the fixed gear (longline and gillnet) having the larger cod share while bottom otter trawl gear have higher haddock quotas. Management has relied primarily on output controls, principally catch quota management. Additional measures have included limited entry licensing, fleet allocations, mesh size/hook size regulation, area/season closures, third party $100 \%$ dockside monitoring to verify species and amounts landed, user pay at sea monitoring, minimum fish size through small fish protocol, mandatory reporting requirements and mandatory landing requirement (no discards).

The following table highlights the recent development of management measures.

|  | USA | Canada |
| :---: | :---: | :---: |
| 1977-82 | Mesh size of $51 / 8^{\prime \prime}(140 \mathrm{~mm})$, seasonal spawning closures (1 March - 31 May), quotas and trip limits. | Catch Quota regulation, seasonal spawning closures (1 March - 31 May) . |
| 1982-85 | All catch controls eliminated, retained closed area and mesh size regulations, implemented minimum landings size $(43 \mathrm{~cm})$. |  |
| $\begin{aligned} & \hline 1984 \\ & \text { Oct. } \end{aligned}$ | Implementation of the 'Hague' line . |  |
| 1985 | $51 / 2 "$ mesh size,. <br> Areas 1 and 2 closed during February-May. |  |
| 1989 |  | Combined cod-haddock-pollock quota for 4X5Zc |
| 1990 |  | $\mathbf{5 Z j m}$ adopted as management unit for cod and haddock. <br> For MG $<65 \mathrm{ft}$. - trip limits with a $30 \%$ bycatch of haddock to a maximum of 8 trips of $35,000 \mathrm{lbs}$. per trip between June 1 and Oct. 31 and 130 mm square mesh required. <br> Fixed gear required to use large hooks until June |
| 1991 | Established overfishing definitions for haddock. | MG $<65 \mathrm{ft}$ similar to 1990 but mesh size increased to 145 mm diamond. |
| 1992 |  | Introduction of ITQs for <65' OT and dockside monitoring. |
| 1993 | Area 2 closure in effect from Jan 1-June30. | OT fishery permitted to operate in Jan. and Feb. Increase in use square mesh. |
| 1994 | Jan.: Expanded Area 2 closure to include June and increased extent of area. <br> Area 1 closure not in effect. <br> 500 lb . trip limit. <br> Catch data obtained from mandatory log books combined with dealer reports (replaces interview system). <br> May: 6" mesh restriction. <br> Dec.: Area 1,2 closed year-round. | Spawning closure extended to Jan. 1 to May 31. Fixed gear vessels must choose between 5 Z or 4X for the period of June to September. <br> Small fish protocol. <br> Increased at sea monitoring. <br> OT $>65$ could not begin fishing until July 1. Predominantly square mesh by end of year. |
| 1995 |  | All OT vessels using square mesh. Fixed gear vessels with a history since 1990 of 25 t or more for 3 years of cod, haddock pollock, hake or cusk combined can participate in 5 Z fishery. <br> ITQ vessel require at least $2 t$ of cod and $8 t$ of haddock quota to fish Georges. |
| 1996 | July: Additional Days-at-Sea restrictions, trip limit raised to 1000 lbs . | Fixed gear history requirement dropped. |
| 1997 | May: Additional scheduled Days-at-sea restrictions. September: Trip limit raised to $1000 \mathrm{lbs} . /$ day, maximum of $10,000 \mathrm{lbs}$./trip. | Vessels over 65 ft operated on enterprise allocations, otter trawlers under 65 ft on individual quotas, fixed gear vessels $45-65 \mathrm{ft}$ on self-administered individual quotas and fixed gear vessels under 45 ft on community quotas administered by local boards. |
| 1998 | Sept. 1: Trip limit raised to 3000 lbs ./day, maximum of 30,000 lbs./trip. | Fixed gear vessels $45-65 \mathrm{ft}$ operated on individual quotas. |
| 1999 | May 1: Trip limit 2,000 lbs./day, max. 20,000 lbs./trip. Square mesh size increased to $6.5 "$ (diamond is 6 "). June 15: Scallop exemption fishery in Closed Area II. Nov. 5: Trip limit 5,000 lbs./day, max. 50,000 lbs./trip. Nov. 15: New overfishing definitions and harvest control rules to comply with Sustainable Fisheries Act. | Same as 1997 and 1998. |
| 2000 | October: Daily trip limit suspended to April 2001but retained max. trip limit of $50,000 \mathrm{lbs}$./trip. | Same as 1999. |

Attachment 2. USA/Canada Statistical Management Units

Note: Unit areas 523 and 524 have been re-designated in the USA statistical system as 551,552 , 561 and 562 , subsequent to 1984 to respect the boundary.

Attachment 3. Description of TRAC Process

## INTRODUCTION

Since the termination of ICNAF in 1977, Canada and the USA have independently developed peer review processes for their stock assessments. In Canada, in late 1992, the Canadian Atlantic Fisheries Scientific Advisory Committee (CAFSAC) was disbanded and the Regional Advisory Process (RAP) put in its place. RAP in the Maritimes Region currently provides advice on about 120 marine and freshwater finfish, shellfish and marine plant resources in the DFO Maritimes Region. In the Northeast Region of the National Marine Fisheries Service (NMFS), the Stock Assessment Workshop (SAW) series was initiated in 1985. The SAW process currently provides advice on about 44 marine finfish and shellfish resources in the Northeast Region of NMFS.

Collaboration between Canada and the USA on stock assessments and related research has been strong. Regular scientific meetings are held to co-ordinate joint research programs and facilitate inter-lab communication. Protocols for routine data exchange, particularly commercial and survey, have been established and joint work on assessment related issues is common. Finally, participation in each other's peer review process is routine.

The 1996 Canada/USA Scientific Discussions noted that it would be desirable to conduct joint assessments of the Georges Bank groundfish stocks during the 1997 assessment cycle. Thus in April 1997, scientists from Canada and the USA combined efforts to prepare assessments of Georges Bank cod, haddock, and yellowtail flounder. The peer review of these assessments was subsequently conducted first by RAP in Canada and then by the SAW Stock Assessment Review Committee (SARC) in the USA. Upon completion of the 1997 process, it was evident that there would be efficiencies realized by eliminating the duplication in the peer review process. This would also ensure that RAP and SARC would not produce divergent and inconsistent status reports on these stocks.

In the fall of 1997, discussions were initiated between the two countries to define a joint peer review process. The Transboundary Resources Assessment Committee, or TRAC, is the result of these discussions. The TRAC process is outlined in the following Sections.

## THE JOINT PEER REVIEW PROCESS

There has been close interaction between Canada and the USA on 5 Z cod, haddock, and yellowtail flounder. To date, these stocks have been the principal focus of the new process, although other "transboundary" resources in the Georges Bank - Gulf of Maine region may be considered in future years.

## Structure of the Peer Review

## Transboundary Assessment Working Group

The Transboundary Assessment Working Group (TAWG) includes Canadian and USA scientists with a range of backgrounds and thus is multidisciplinary in nature. As well, industry participation from both countries are encouraged. Its mandate is to:

- analyze pertinent assessment information and produce stock assessments on identified stocks; and
- formulate research recommendations which will lead to long-term improvements in the assessments.

Meetings of the TAWG are arranged on a mutually agreed basis by both countries. The TAWG is co-chaired by a stock assessment scientist from each country. Annual meetings will be held alternately in Canada and the USA to prepare assessments and to address other issues as requested by the TRAC.

## Transboundary Resources Assessment Committee

The Transboundary Resources Assessment Committee (TRAC) has been established to peer review stock assessments produced by the TAWG. The TRAC is distinct from RAP and SARC. The Committee is co-chaired by representatives from Canada and the USA who are responsible for all logistical arrangements associated with TRAC meetings (e.g., dates, venue, participation).

As for the TAWG, the TRAC will alternate its venue between Canada and the USA. The TRAC is responsible for producing final, approved assessments and resulting documentation on the status of the transboundary resources.

Participation is by invitation and will include stock assessment scientists, fisheries managers, and industry representatives from both countries. While there are currently no limitations on numbers of participants it is likely that 10-15 participants from both countries will attend future meetings.

## TRAC Coordination

The RAP and SARC Chairs, with the guidance of their respective steering committees, oversee the activities of the TRAC and TAWG.

## $\underline{\text { Management Advice and Public Meetings }}$

Once the TRAC review process has completed its deliberations, the results may be used by either country for fisheries management purposes as appropriate e.g., preparation of management advice in Canada by the Fisheries Resource Conservation Council (FRCC) and in the USA by the Multispecies Monitoring Committee (MMC). Each country may conduct independent consultations with clients or disseminate the information to the public, informing the other side as required.

## Stock Status/Advisory Documents

The purpose of the joint Canada/USA stock assessment process for transboundary resources is only to produce and peer review assessments of stocks of mutual interest and not to prepare management advice. The assessment results from this joint process will be used by each country for their respective fisheries management purposes. The document series currently employed by
each country to convey a brief summary of stock status and management advice for individual stocks (i.e., the DFO Stock Status Report series in Canada and the SAW Advisory Report on Stock Status in the USA) will continue to be used for those purposes in each country. In addition, more comprehensive research reports will be produced for the Canadian Research Document Series under the auspices of the Canadian Stock Assessment Secretariat and the USA NEFSC Research Reference Document series.

Attachment 4. Summary of Current Management Systems and Processes
In Canada, the Department of Fisheries and Oceans will advise the Minister of Fisheries and Oceans of the findings of this group. The Minister will also be advised of the results of the TRAC process, which identifies the consequences of alternative harvest levels on F and biomass reference points (taking uncertainty into account). Additionally, the FRCC provides advice to the Minister based on their review of the available science and their consideration of stock objectives, including an exploitation rate, spawning stock biomass threshold, and expectations of rate of increase in biomass. The Minister will consider these findings to establish an appropriate harvest level for each stock. While there is an F reference point (usually $\mathrm{F}_{0.1}$ ), neither F nor the TAC is prescribed by the scientific analysis. The Minister usually makes his recommendation in May for a fishing year beginning in June.

In the USA, the New England Fishery Management Council will be advised of the Steering Group recommendations. The Council will consider this information during their annual meetings to establish the TAC and management measures for the subsequent fishing year. For cod, haddock, and yellowtail flounder, the fishing year runs from May through April, and the annual management measures are discussed at two meetings starting in November. At the November meeting, the Council receives the recommendations of the Multispecies Monitoring Committee (MMC). The MMC reviews the effectiveness of the previous year's management measures and considers the TRAC and other stock assessment results, and makes recommendations on the appropriate target TACs and management measures necessary to constrain fishing effort to the allowable F. The F is prescribed by the Northeast Multispecies Fishery Management Plan.

Yellowtail in Div. 5Z ..... 32
Fishery Landings ..... 32
Surveys ..... 34

## Terms of Agreement

There was agreement that USA and Canadian scientists should develop a common database regarding transboundary resources for the Transboundary Management Guidance Committee (TMGC). The following Terms of Agreement were accepted for the technical group:

For transboundary resources, establish a common database covering as long a time period and as fine a spatial scale as reasonable, including:
(a) historical catch data
(b) research vessel survey data
(c) biological information on migration patterns, spawning areas and nursery grounds

A general database of historical catch data, and perhaps research vessel survey data, will be prepared for transboundary resources for which data are available. The USA and Canada then need to come to agreement on issues such as data gaps, data sources, interpretations, limitations, etc. Data regarding Transboundary Resource Assessment Committee (TRAC) species have already been processed as part of the TRAC process and are ready to be compiled in a more detailed "pilot" database. Therefore, TRAC species (cod, haddock, yellowtail, and, soon, herring) will be given priority by the Technical Working Group. The availability and quality of data in the broad database may indicate which additional species on Georges Bank require transboundary management.

## Introduction

On 5 May 2001 the TMGC was provided with a pilot database of fisheries and bottom trawl survey information for cod, haddock and yellowtail. At the 13-16 May 2001 meetings of the TMGC and the Steering Group, while database limitations were recognized, it was agreed that this database offered a suitable basis for considerations regarding consistent management. To facilitate such considerations, further summarization and compilation were requested. Specifically,

- Summarize the catch data for cod, haddock and yellowtail as annual totals by Canada and USA.
- For cod and haddock, the catches should be provided for 2 zones, eastern Georges Bank (5Zej and 5Zem or 523 and 524) and western Georges Bank (the remainder of 5Z); it is understood that after 1984, the USA and Canadian catches from eastern Georges Bank were taken on the respective sides of the boundary.
- Estimate the biomass index for strata sections that are partitioned by the international boundary and, for cod and haddock, also by the 5Zej and 5Zem unit area boundaries.
- Summarize the biomass indices by Canada and USA sides of the boundary for each survey for Georges Bank (all of 5Z).
- For cod and haddock, summarize the biomass indices by Canada and USA sides of the boundary for each survey for eastern Georges Bank (5Zej and 5Zem or 523 and 524).
- Interpret any seasonal and annual variations in the biomass distribution.

This document should be considered an adjunct to the pilot database provided on 5 May 2001. Accordingly, figures and tables in that document are not reproduced here.

## Notes

These notes are intended to assist interpretation of results.

- There are slight differences between the NMFS area 524 and the DFO area 5 Zm boundaries.
- For 5Ze jm haddock results, DFO stratum 5Z8 and NMFS strata 29 and 30 were not included as per the assessment.
- For missing strata or strata sections, density and distribution patterns from adjacent areas and years were used to estimate values. This procedure required judgement, however, the biomass contributed by the missing strata or strata sections was generally small and should not unduly influence results.
- Discrepancies in resolution between GIS software and coded strata/area may introduce some minor distortions, but these should not significantly influence results.
- Caveats, footnotes and qualifications given for the 5 May 2001 pilot database also apply here.

## US TMGC PROPOSED SHARING AGREEMENT WITH CANADA FOR COD, HADDOCK, AND YELLOWTAIL FLOUNDER

## Overview of Principles

The US TMGC applied the following principles for the proposed sharing agreement for cod, haddock and yellowtail: (1) Data from time periods representative of rebuilt stock distribution were selected. (2) Whole-Bank stock structure is assumed in this proposal. A scientific review of the best available information on haddock and cod stock structure on Georges Bank is needed, preferably through TRAC and in the near future. The review of the best available information may cause us to reconsider our position regarding whether to manage haddock and cod as one or two stocks. If the two-stock option is selected, the sharing formula should reflect this change, using the same data-periods and principles. (3)Landings and survey data are adopted as equally important criteria. (4) Historical investment in research is considered important, but only a rough proxy is easily calculable therefore this criteria is weighted lower than landings and survey data. Justification for the criteria selected for the proposed sharing agreement and the data time periods selected as representative of rebuilt stock distributions is given below.

## Landings Data

Most fish allocation agreements, whether between countries, industry sectors, or states, take historical landings patterns into account at least to identify valid participants. The UN Fish Stocks Agreement lists fishing practices, patterns, and community dependence among the few criteria to be considered when determining participatory rights of new members of fishery management organizations. Historical landings provide a proxy for less quantifiable elements that determine the importance of fisheries for a particular country or, in local fishery management decisions, a sector of the industry. Landings provide some insight into elements such as historical investment in the development of the fishery, economic dependence, cultural identity, and heritage.

The allocations in the unratified 1979 US-CDA East Coast Fishery Treaty were based largely on landings records between 1965 and 1977. While this time period does not fully capture the historical importance of the Georges Bank groundfish fisheries upon which the first New England settlements were founded, this Treaty represents the most recent attempt to identify US and Canadian entitlements to Georges Bank fish. The allocations of Georges Bank stocks within the disputed fishing area (prior to the Hague Line decision) proposed under the treaty gave the US $83 \%$ of the cod, $79 \%$ of the haddock, and approximately $99 \%$ of the yellowtail flounder (Canada was given $1 \%$ of yellowtail landings in area 5 and 6 ). Although the basis for the proposed treaty did not fully consider the historical importance of Georges Bank to US fishers, these proposed allocations provide the most valid starting point for discussions of future sharing agreements with Canada.

Fishery management decisions in the USA are based on rebuilding overfished stocks to target stock biomasses that produce MSY. Landings data from the period for which stocks were healthy best reflect the yield potential of a rebuilt stock. The US TMGC applied landings data
from the time periods for which the cod, haddock, and yellowtail stocks on Georges Bank were at target biomass levels. Additionally, we recognized the importance of the consensus decision of the US/CDA TMGC and the Transboundary Steering Committee to disregard landings data after 1994, when cod and haddock stocks collapsed and severe management measures were implemented. Landings during that rebuilding period do not reflect interest, capacity or perceived entitlements.

## Survey Information

The distribution of the stocks on either side of the Hague, or ICJ, Line must be considered when identifying USA and Canadian allocations. Each country considers its fishers to be entitled to the resources that occur in their respective waters. In the case of these resources, seasonal variation in the percentage occurring on either side of the boundary is significant. Thus neither side can claim percentage entitlement based on the maximum fraction of the stocks occurring in their zone in a particular season. If a uniform harvest strategy is one of the goals of management measures or the allocation agreement, consideration of the distribution of stocks across Georges Bank should equal the claims based on historical distribution.

However, existing survey data are insufficient to design an absolutely uniform harvest strategy across any given year. Fish move throughout the year, and the 3 distinct annual surveys conducted to assess the relative abundance of these stocks merely provide regular snapshots of distribution. For all three stocks, there is significant variability in the fractions of stocks occurring on either side of the boundary over time that may be explained by changes in abundance or by unidentified shifts in environmental conditions. Relying only on current distribution data or using a short time period would only be valid if the sharing agreement is going to be recalculated annually. Given the large inter-annual variability possible in these data, such annual recalculations and resultant fluctuations in allocations would be unpopular with fishers that rely on these stocks and who require predictable allocations to support basic business decisions.

As discussed above, these stocks are currently being managed to rebuild stock abundance, age structures and spatial distributions. The distribution of these stocks during periods of relative abundance best mirrors the distribution we anticipate once the stocks have recovered and reached their target biomass levels. Therefore survey data from these rebuilt time periods were selected in developing the proposed sharing agreement.

The proportional distribution of these stocks based on the time series of fish abundance data was determined from standardized bottom trawl surveys conducted on Georges Bank. The primary survey series used were the USA spring and autumn surveys since they are continuous, have approximately equal sample density (stations per square mile) over the entirety of the Bank, and were conducted over long time periods that span times of resource abundance and depletion. A straight average of the USA spring and autumn data was used to compute the fraction of stocks occurring on the USA and Canadian sides of the ICJ line. A finer resolution in time (e.g., by month) is not possible, but the spring and autumn time periods approximately correspond to the annual bottom temperature minima (spring) and maxima (autumn), and patterns of distribution between the two surveys do seem to illustrate large-scale movement patterns especially characteristic of cod and haddock. The Canadian survey series was not incorporated into the
proposals because of the variable sampling effort and short time series available. There were some years (>93->94) when no stations were surveyed in the western-most strata in the Canadian survey or wherein the sample density was lower in the west (reflecting different levels of survey precision across the Bank). Additionally, the database does not extend back long enough in time (i.e., only back to 1987) to allow the calculation of resource spatial distributions associated with time periods in which the stock abundance was considered high and at target levels (e.g. 60s1982 for haddock, 60 s -1990 for cod, 60 s -2000 for yellowtail).

## Historical Investment in Science

Just as landings data are a rough proxy of the historical, cultural investment in a fishery, many international allocation agreements also give strong consideration to investments in scientific research that provide the data that enable us to assess the status of the stocks and support current management goals, objectives, and decisions. Historical investment in research is difficult to quantify, as broad research efforts have been conducted that include surveys, life history studies, sea sampling efforts, and numerous other investigations. As a simple proxy, we have selected the relative number of research surveys as a rough indicator of historical investment. There have been a total of 85 surveys conducted; 71 ( $84 \%$ ) by the US and 14 ( $16 \%$ ) by CDA. Because this proxy is imprecise, this criteria is given only half the weight of the other two in our sharing formula.

## Results

## HADDOCK

Time period selected: For landings data, the 1967-1982 period was chosen to reflect the spatial distribution of a rebuilt stock. This period does not necessarily reflect the yield potential of the rebuilt stock (e.g. the database used by the TMGC begins in 1967, after the very large 1962 and 1963 year classes had been depleted) but does reflect two time periods when western and eastern stock components both contributed significantly to the catches. The use of the 1967-1982 period for landings is intended to encompass the remnants of the early 1960s year classes, as well as the relatively large 1975 and 1978 year classes that temporarily reversed resource depletion, while for survey data, the 1963 (fall)/1968 (spring) to 1982 period was chosen. Fishery managers in the USA have established target stock biomasses for haddock that, on average, should avoid recruitment overfishing and produce MSY. These levels were last observed in the 1960s and again nearly so in the late 1970s to early 1980s. The full time series of landings do not necessarily reflect the yield potential of the rebuilt stock (e.g. the database used by the TMGC begins in 1967, after the very large 1962 and 1963 year classes had been depleted) but do reflect two time periods when western and eastern stock components both contributed significantly to the catches. The use of the 1967-1982 period for landings is intended to encompass the remnants of the early 1960s year classes, as well as the relatively large 1975 and 1978 year classes that temporarily reversed the scenario of resource depletion. Likewise, the 1963 (fall) and 1968 (spring) to 1982 period used as the averaging period for surveys is intended to be consistent with the philosophy of indexing, as best as possible, a time period reflecting the rebuilt stock condition considering the large year classes of the early 1960s and mid-late 1970s. The average proportion of landings and biomass occurring on the USA side of the boundary during the pre1983 period are almost identical. Current stock size for haddock is again approaching target
biomass levels, with greater fractions of the haddock resource now accumulating on the USA side, consistent with the pattern observed in the pre-1983 period. However, the landings fractions accruing on each side of the ICJ line are now skewed by differences in management between the two countries.

Sharing formula: Note: proposed shares expressed as a fraction of fishing mortality rather than weight to allow for evaluation of conservation equivalency of varying management measures

```
L=US \% landings; \(D=\) distribution, \% in US waters; \(S=\%\) Surveys by US
US allocation \(=.4(\mathrm{~L}\) from 67-82)+.4(D from 63-82)+.2(S)
US haddock allocation \(=.4(72 \%)+.4(70 \%)+.2(84 \%)=74 \%\)
```

## COD

Time period selected: For landings data, the 1967-1990 period was chosen to reflect the spatial distribution of a rebuilt resource, while for survey data, the 1963 (fall)/1968 (spring) to 1990 period was chosen. The period through 1990 reflects generally rebuilt conditions, although the biomass targets have not been approached since the 1980s. A succession of large year classes ( $1978,1980,1983,1985$ and 1987) supported relatively high landings throughout the 1980s. High landings were also observed in the 1960s and early 1970s, probably supported by the 1965 and 1970 year classes. The use of the 1967-1990 landings period and the 1963 (fall)/1968 (spring) to 1990 survey averaging periods reflect the Bank-wide distribution that can be expected from the presence of these dominant large year classes.

Sharing formula: Proposed shares expressed as a fraction of fishing mortality rather than weight to allow for evaluation of conservation equivalency of varying management measures

```
L=US \% landings; \(D=\) distribution, \% in US waters; \(S=\%\) Surveys by US
US allocation \(=.4(\mathrm{~L} 67-90)+.4(\mathrm{D} 63-90)+.2(\mathrm{~S})\)
US Cod allocation \(=.4(75 \%)+.4(73 \%)+.2(84 \%)=76 \%\)
```

## YELLOWTAIL FLOUNDER

For yellowtail flounder, the entire time series is averaged to reflect rebuilt stock spatial distribution. During the period from 1963 to present, the yellowtail flounder stock has fluctuated significantly in abundance reflecting the production of strong and weak year classes and the overall level of fishing mortality. Yellowtail biomass peaks occurred during three periods; in the 1960s to early 1970s, in the late 1970s to early 1980s, and again in the period since 1998. In the intervening years yellowtail abundance and landings were relatively low. Selecting a period over which to determine the spatial distribution of yellowtail consistent with a rebuilt stock status is complicated by the fact that spatial distribution patterns in the most recent period of abundance show somewhat different patterns than during the previous periods of high abundance. It is clear that factors other than stock abundance can influence the relative distribution of yellowtail flounder on either side of the ICJ line. Since the relative distribution patterns have varied even when the stock was "rebuilt", the entire time series (1963/68-2000) of survey data was averaged
to reflect the uncertainty in long-term distribution patterns. Landings data for the entire period, until 1994, were selected to reflect this distribution of the rebuilt resource while excluding the period of severe management regimes.

Sharing formula: Proposed shares expressed as a fraction of fishing mortality rather than weight to allow for evaluation of conservation equivalency of varying management measures
$\mathrm{L}=$ US \% landings; $\mathrm{D}=$ distribution, \% in US waters; $\mathrm{S}=\%$ Surveys by US US allocation $=.4(\mathrm{~L} 67-94)+.4(\mathrm{D} 63-00)+.2(\mathrm{~S})$
US yellowtail flounder allocation $=.4(98 \%)+.4(73)+.2(84 \%)=85 \%$

## Attachment 7

## RESOURCE SHARING PROPOSAL

Submitted By: Canadian Team to TMGC
22 August 2001
The Georges Bank cod, haddock and yellowtail resources are entirely within USA and Canadian exclusive economic zones and the objective of our mutual collaboration is to achieve consistency of management measures applied to their respective territories. As directed at the recent (May 16, 2001) Transboundary Management Guidance Committee (TMGC) Steering Committee the following proposal on sharing arrangements is submitted by the Canadian members of the TMGC working group.

This proposal recognizes two key principles for determining shares of the transboundary resources of cod, haddock and yellowtail, resource utilization and resource distribution. Resource utilization is reflected by the landings while resource distribution is derived from survey results.

## Resource Utilization

Both Canadian and USA members of the Steering Committee agree on the landings history for both Canada and USA for the period from 1967 to 2000 . The international maritime boundary between USA and Canada on Georges Bank was established in 1984 and subsequent fishing by USA and Canada has been conducted within each country's respective territory. In recognition of this fundamental change that occurred in 1984, it is considered that the landings history prior to 1985 is not relevant to the current or future opportunities for utilization of these transboundary resources for either country. Accordingly, the Canadian proposal advances the use of the average percentage landed by USA and Canada between 1985 and 2000 as the basis for reflecting resource usage.

1985-2000

|  | COD (5Z) |  | COD (5Zjm) | HAD (5Z) |  | HAD (5Zjm) |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | YELLOWTAIL

## Resource Distribution

The agreed to database includes the survey results for NMFS fall surveys from 1963 to 2000, for NMFS spring surveys from 1968 to 2000 and for DFO surveys from 1987 to 2001. While survey results are variable and show annual fluctuations, examination of these results confirms that persistent changes in resource distribution relative to the international maritime boundary have occurred in the past.

To account for temporal shifts in resource distribution while moderating ephemeral year to year differences, the Canadian proposal advances the use of the average percentage of survey biomass in respective territories between 1991 and 2000. For cod and haddock on eastern Georges Bank
( 5 Zjm ), these surveys indicate a seasonal migration pattern, westward between fall and spring and eastward between spring and fall. This migration pattern is not as obvious for cod and haddock on Georges Bank (5Z), probably due to the confounding by the movements of the Southwest Channel components. To account for this seasonal migration, for cod and haddock, the NMFS spring (March) and DFO (February) surveys are each given $25 \%$ weighting while the NMFS fall (October) survey is given $50 \%$ weighting. For yellowtail, the three surveys are averaged without weighting.

1991-2000

|  | COD (5Z) |  | COD (5Zjm) | HAD (5Z) |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
|  |  | HAD (5Zjm) | YELLOWTAIL |  |  |
| USA | $63 \%$ |  | $16 \%$ | $34 \%$ |  |
| CDN | $37 \%$ | $84 \%$ | $66 \%$ |  | $12 \%$ |
|  |  | $88 \%$ | $52 \%$ |  |  |
| CD |  |  |  |  |  |

## Sharing Formula

Both countries have accepted that resource utilization and distribution are key principles for developing any resource sharing formula. The relative importance of each principle in determining sharing arrangements must be established. The Georges Bank cod, haddock and yellowtail resources are entirely within USA and Canadian exclusive economic zones and the objective is to achieve consistency of management measures applied in their respective territories. In this circumstance historical resource utilization has little relevance while resource distribution is directly associated with achieving this objective. Accordingly, the Canadian proposal attributes less importance to resource utilization and advances a weighting of $95 \%$ to resource distribution and $5 \%$ to resource utilization. The resulting allocation shares are:

|  | COD (5Z) |  | COD (5Zjm) | HAD (5Z) |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| HAD (5Zjm) | YELLOWTAIL |  |  |  |  |
| USA | $63 \%$ |  | $17 \%$ | $34 \%$ |  |
| CDN | $37 \%$ | $83 \%$ | $66 \%$ |  | $12 \%$ |
|  | $88 \%$ | $53 \%$ |  |  |  |
|  |  |  |  |  |  |

The Canadian proposal for the larger 5Z management units of cod and haddock implicitly assumes that additional effective management would be taken to reflect any heterogeneous area patterns in these stock complexes

## Terms of Reference

Purpose: Given the wide disparity in the resource distribution implied in both the USA and Canadian resource sharing proposals, a sharing agreement based on distribution that was more sensitive to the rate of change was preferred to the two extreme proposals offered. The following terms of reference (TOR) will provide data to the TMGC to develop a flexible mechanism for responding to change in distribution.

- Develop and illustrate methods to provide near-term forecasts of resource distributions using finfish surveys.
- Examine the sensitivity of results to averaging period, calculation method (weighting of surveys and methods to combine percentages), time tapering for weighting results, and other factors, as appropriate.
- Apply the methods developed to the time series of survey data to evaluate the historical performance of the method in relation to implications for fishery resource sharing.

## Introduction

Bottom trawl surveys can be used to determine the distribution of groundfish resources relative to the USA/Canada maritime border. Results from three surveys, the NMFS spring, the NMFS fall and the DFO surveys are available. This task raises two issues:

- how to combine the three surveys; and
- how to smooth undesirable annual variation.

Each of these issues is dealt with separately and possible options are identified along with their strengths and weaknesses.

## Combining the Surveys

The issue of how to combine the three surveys concerns understanding of seasonal migration patterns. Ideally, information on the resource distribution for many times during the year, if it were available, could be integrated over the year to get an annual average. The three available surveys are generally conducted in February, March and October. Additional observations from fishery catches and studies of spawning behaviour can help interpret how the surveys are used. Marked migrations have not been noted for yellowtail while cod and haddock are thought to migrate to shallower depths on the Bank for spawning during the colder winter-spring season and move to the deeper slopes during the warmer summer-fall season. In accord with this view, the resource distribution results for yellowtail do not show persistent seasonal patterns for yellowtail between the three surveys. Resource distribution results for cod and haddock in 5 Zjm show a distinct pattern consistent with the spawning behaviour. Resource distribution results for cod and haddock in 5 Z as a whole are less clear and may be confounded by migrations during the summer-fall to the deeper slopes of both the South Channel and the Northeast Peak.

If marked migrations are not a major feature, each survey can be viewed as an equally representative and independent observation of the average annual resource distribution. A simple average of the available surveys in any year provides an estimate of the resource distribution that makes best use of all the data. It is recommended that a simple average of available surveys in each year be used for yellowtail.

If marked migrations are an important feature, each survey can be associated with the season it represents. A simple average of surveys that occur during the same season can be used to combine within a season. Seasonal results can then be combined, taking into account the duration of the seasons. For example, the cod and haddock resource distribution results from the NMFS spring and DFO surveys can be averaged to characterize the colder winter-spring period and subsequently combined with the NMFS fall survey that depicts the warmer summer-fall period. While this may be a reasonable interpretation of the distribution patterns for cod and haddock, consistent with our understanding of their biology and spawning behaviour, the limitations of using three "snapshots" to interpret a continuous migration process leave any scheme for combining the surveys open to criticism. Consequently, it is not possible to recommend a single unequivocal approach for combining the survey results of cod and haddock. Rather, we submit two options for your consideration

- Average of 2 seasons:

1. Average NMFS spring and DFO surveys, or use the NMFS spring (prior to 1987) to characterize distribution during the colder winter-spring period.
2. Use the NMFS fall survey to characterize distribution during the warmer summer-fall period.
3. Combine the two periods assuming equal duration.

- Average of 3 surveys:

1. Use a simple average of available surveys in each year.

## Smoothing Annual Variation

What is desired is a reliable near-term (1-3 years) forecast of resource distribution. Annual observations display considerable dispersion. Some of this dispersion is due to real, but unpredictable, fluctuations in resource distribution. These "high frequency" fluctuations do not tell us much about near-term forecasts. Another component of the dispersion is due to statistical sampling variation. The intent is to remove both the high frequency fluctuations and the sampling variations. One way of doing this is to apply a "scatterplot smoother". Because scatterplot smoothers are a "descriptor" of existing data, extrapolation beyond the data requires judgement. In order to avoid imposing questionable model assumptions, it is recommended that the scatterplot smoothers are applied to the available time series and the results for the last observation be accepted as the near-term forecast.

For our problem, another consideration is at what stage to apply the scatterplot smoother. The smoother can be applied to each of the indices to obtain smooth indices from which resource distribution for each survey can be derived and subsequently combined. Alternatively, the resource distribution for each survey may be derived using the observed data, subsequently combined and the smoother applied as the final step. Applying the smoother at some intermediate step is also possible. It is recommended that applying the scatterplot smoother only once, as the final step of the analysis, offers a more transparent process that is less subject to complications.

A generally accepted "scatterplot smoother" is the robust locally weighted regression, referred to as loess. Unfortunately, these tools, while useful, involve some subjective judgement. Loess requires two subjective inputs, a) the fraction of data used to obtain the "smooth" at any point, and $b$ ) the number of iterations for robustness. Available guidelines suggest that the fraction of data be between $20 \%$ and $80 \%$ with $50 \%$ as a reasonable compromise. Experience suggests that most of the benefits associated with the robustness algorithm are achieved in two iterations. It is recommended that the default of two robustness iterations be used unless this results in inconsistencies. We submit results using $30 \%, 50 \%$ and $70 \%$ as the fraction of the data included in the local regressions. The $30 \%$ value corresponds to a time window of approximately 10 years, to contrast against the default of $50 \%$. The $70 \%$ value is used to illustrate a "more" smooth scenario.

A point for future consideration is whether it would be desirable to reduce the fraction of data included in the local regression as the time series is augmented in order to maintain a roughly consistent time window.

## Summary and Results

For yellowtail the surveys are combined using a simple average of surveys available in each year. For cod and haddock, two options for combining surveys are provided, one reflecting understanding of migration and the other a default simple average. The robust locally weighted regression scatterplot smoother is applied as the final stage of the analysis to the combined percent distribution. Results are presented for $30 \%, 50 \%$ and $70 \%$ as the fraction of the data included in the local regressions.

## GUIDANCE ON OPTIONS FOR DETERMINING PERCENTAGE OF RESOURCE SHARE

Prepared by: Transboundary Management Guidance Committee
5 December 2001

## Introduction

At it is inaugural meeting on 13 September 2000, the Transboundary Management Guidance Committee was charged with establishing rules and clarifying its work mandate. The following Terms of Reference were agreed:

1. Recommend F-based harvesting strategies that are consistent with US and Canadian objectives. (and laws).
2. Provide guidance on options for determining percentage of resource share.
3. Develop process for implementation of TMGC's recommendations.
4. Make recommendations for actual US and Canadian harvest levels.
5. Make other recommendations that are mutually beneficial to US and Canadian fisheries.

This report addresses Term of Reference \#2.

## Procedure

It was agreed to apply an approach that accounts for historical utilization and that adapts to shifts in resource distribution. The sharing agreement applies to the following management units: haddock 5 Zjm , cod 5 Zjm , and the entire Georges Bank yellowtail flounder. There are four major components to the agreement:

- The use of resource survey data based on the three bottom trawl surveys (NMFS spring, DFO winter and NMFS fall) to calculate the annual proportion of the resource on either side of the boundary. After combining the percent resource distribution from the three surveys, $30 \%$ loess smoothing was applied to the most recent 33 years. This same procedure ( $30 \%$ loess smoothing applied to the most recent 33 years) will be used to update resource distribution.
- Historic proportions of fishery landings data calculated from the period 1967-1994 inclusive.
- The following formula was agreed for calculating the respective country shares:
$\%$ country share $=\alpha_{\text {year }}$ country utilization $+\beta_{\text {year }}$ resource distribution
where $\alpha_{\text {year }}=$ percentage weighting for utilization in year
$\beta_{\text {year }}=$ percentage weighting for distribution in year
$\alpha_{\text {year }}+\beta_{\text {year }}=100 \%$
country utilization $=$ 1967-1994 historic catch percentage share
resource distribution $=30 \%$ loess smoothing of most recent 33 years
- Initial sharing formulas are based on proportions of resource distributions from surveys ( $60 \%$ of the formula) and average percentages of the 1967-1994 landings by country ( $40 \%$ of the formula). The percentage weighting would change in equal increments from the starting point to $90 \%$ (resource surveys) and $10 \%$ (fishery landings data).
- Starting date for the agreement is 2003 , with the end of the transition to a $90 / 10$ weighting formula in the 2010 fishing year according to the following schedule.

| 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| $60 / 40$ | $60 / 40$ | $65 / 35$ | $70 / 30$ | $75 / 25$ | $80 / 20$ | $85 / 15$ | $90 / 10$ |

- The resource sharing allocations will be updated annually to reflect shifts in resource distribution. The catch distributions used in the sharing formula remain fixed according to the 1967-1994 period and are:

|  | USA |  | CANADA |
| :--- | ---: | ---: | ---: |
| COD (5Zjm) | $40 \%$ |  | $60 \%$ |
| HADDOCK (5Zjm) | $45 \%$ |  | $55 \%$ |
| YELLOWTAIL | $98 \%$ |  | $2 \%$ |

- Update of the database on resource distribution will occur as soon as possible after completion of a calendar year and no later than February $15^{\text {th }}$. The calculation of updated percentage of resource sharing allocations will be reviewed by TMGC no later than April $1^{\text {st }}$.
- TMGC will draft an advisory communication, to be conveyed to fisheries management authorities in Canada and USA, reporting on the determination of percentage of resource sharing allocations for fishing years for which management plans are being developed. It will be recommended that respective Canadian and USA fisheries management plans be based on the same determination for a fishing year most closely corresponding to the calendar year. For example, the USA fishing plans for May 2003-April 2004 and Canadian fishing plans for Jan-Dec 2003 would both be based on the determination made using end of year 2001 information.

For each of the resources, details of the survey series mixing and specific starting conditions based on current resource distributions would be:

## GEORGES BANK YELLOWTAIL

The management unit for which this agreement applies is the entire Georges Bank yellowtail flounder resource. Resource distributions based on research vessel surveys use the three surveys equally weighted. The calculated proportions of the resource on each side of the boundary in 2000, based on smoothed survey data are Canada $46 \%$ and USA $54 \%$. Based on catch distributions (for 1967-1994), current information on resource distribution and a weighting factor of 60/40 for initial allocations, the starting allocations would be:

Canada Proportion: 28\%
USA Proportion: 72\%

## Without change in the resource distribution, the allocations in 2010 would be:

Canada Proportion: 42\%
USA Proportion: 58\%

## 5Zjm HADDOCK

The management unit for which this agreement applies is the 5 Zjm haddock resource. Resource distributions based on research vessel surveys use the three surveys equally weighted. The calculated proportions of the resource on each side of the boundary in 2000, based on smoothed survey data are Canada $80 \%$ and USA $20 \%$. Based on catch distributions (for 1967-1994), current information on resource distribution and a weighting factor of 60/40 for initial allocations, the starting allocations would be:

## Canada Proportion: 70\%

 USA Proportion: 30\%Without change in the resource distribution, the allocations in 2010 would be:
Canada Proportion: 77.5\%
USA Proportion: 22.5\%

## 5Zjm COD

The management unit for which this agreement applies is the 5 Zjm cod resource. Resource distributions based on research vessel surveys use the two seasons equally weighted, with DFO and NMFS spring surveys averaged to represent the winter-spring season and the NMFS fall survey representing the summer-fall season. The calculated proportions of the resource on each side of the boundary in 2000, based on smoothed survey data are Canada $82 \%$ and USA $18 \%$. Based on catch distributions (for 1967-1994), current information on resource distribution and a weighting factor of 60/40 for initial allocations, the starting allocations would be:

Canada Proportion: 73\%
USA Proportion: 27\%

## Without change in the resource distribution, the allocations in 2010 would be:

Canada Proportion: 80\%
USA Proportion: 20\%

Attachment 10: Summary of Stock Status

YELLOWTAIL FLOUNDER: Following a steady decline from the early 1970s, biomass increased in the early 1980s due to the strong 1980 year-class, then decreased to historic lows. Biomass increased 10-fold since 1995, and is at the highest observed level since 1973. However, the age structure remains truncated and dominated by younger ages. Recent recruitment is strong, with an outstanding 1997 year-class and above average 1996, 1998 and 1999 yearclasses. Exploitation was generally above $50 \%$ since the 1970s but declined markedly after 1994 reaching about $15 \%$ in 2000. However, exploitation on ages 2 and 3 has not declined proportionally and the partial recruitment to the fishery for these ages has increased.

HADDOCK: Biomass has steadily increased more than 5-fold since 1993 from near historic low levels due to higher survivorship and improved recruitment since 1992, but remains below the 1930-55 average. The 1998 and 2000 year-classes are estimated to be the strongest since 1978. The 1996 and 1999 year-classes were estimated to be the third and fourth largest since 1978. A broad age structure is reflected in both the fishery catch and the population and age $4+$ biomass is at its highest level since 1982. Exploitation has been reduced to below $20 \%$ from pre-1994 levels that peaked at about $40 \%$, but has increased slightly in each of the past three years.

COD: Biomass declined between 1980 and 1985, increased in 1988, and subsequently declined to a record low in 1994/1995. Biomass has since gradually increased as a result of growth and survival of recent year classes rather than improved recruitment. Since the 1990 year-class, the sizes of recruiting year-classes have all been well below average. The 1997 and 2000 year classes are estimated to be the weakest in the time series. Exploitation reached a record high of over $50 \%$ in 1994 but has since declined to below $20 \%$. Without improved recruitment biomass rebuilding is unlikely.
